## Coating

**081494 SLIP MIGRATION IN EXTRUSION COATINGS.** This article presents the results of timed CoF studies and examines the migration rates and surface modifications of five commonly used slip agents as a function of slip-agent type, substrate porosity, slip concentration, and coating thickness. The ability of a slip agent to reduce the coefficient of friction on a polymer surface depends on the type and concentration of amide being used, the porosity of the substrate, and the thickness of the polyethylene coating.

**Components** See PARAFFINS—Diffusion.

## Compressibility

**081495 THERMODYNAMIC INVESTIGATION OF UNIAXIAL TENSION OF POLYETHYLENE ORIENTED IN HEPTANE.** The processes of uniaxial tension and compression of polyethylene subjected to drawing in heptane, which has a plasticizing action, are studied by deformational calorimetry. On the basis of the relations obtained for the work done, the thermal effect, and the changes in internal energy as a function of elongation, a thermodynamic analysis of the deformation process is presented. It is found that the ability of PE to store internal energy under irreversible tension is inversely related to the drawing elongation factor of the PE previously drawn in heptane. Accordingly, the transition from the stage of elastic tension to that of transition to oriented drawing is accompanied by the appearance of residual elongations and evolution of a considerable quantity of heat. The structural rearrangements thus taking place are characterized by accumulation of internal energy. (Edited author abstract) 9 refs.

**Conductive** See COMPOSITE MATERIALS—Injection Molding.

**Contamination** See Also ELECTRIC INSULATION—Thermodynamics.

**081496 NUCLEATION OF ELECTRICAL TREES IN POLYETHYLENE.** The inception voltage for 1-pC partial discharges has been measured for vacuum-molded needle-plane samples of low-density polyethylene. The principal parameters studied are needle radius  $R$  ( $3 < R < 100 \mu\text{m}$ ), ambient gas (air,  $\text{N}_2$ , Ar,  $\text{SF}_6$ ), and frequency of the applied ac voltage (60 Hz, and 1 kHz). Experimental results during this nucleation phase indicate that electrons, field-emitted from the needle tip, transit through microvoids in the polymer before being stopped by collision with polymer chains. During transit they interact with molecules of the particular ambient gas that permeate the polymer's 'free volume'. In spite of the extremely small size of microvoids, Townsend avalanche-like behavior is inferred. 25 refs.

## Corrosion Protection

**081497 EFFECT OF NDA AND G-2 CORROSION INHIBITORS ON THERMO- AND PHOTOOXIDATIVE DEGRADATION OF POLYETHYLENE FILM.** The protective capacity of polyethylene films containing volatile inhibitors of metal corrosion is up to 20 times higher than that of conventional films. Taking into account the known processes of degradation of PE the authors examined the effect of volatile corrosion inhibitors on the basis of low-molecular amines on the stability of its properties. Industrial inhibitors of metal corrosion NDA and G-2 were added to high-density and low-density polyethylene. The compounds act as inhibitors of metal corrosion and also processes of photo- and thermal oxidation of polyethylene and stabilize its strength properties. 6 refs.

**Crack Propagation** See Also PIPE, PLASTIC—Testing.

**081498 J-INTEGRAL CORRELATION OF THE INITIATION OF SLOW CRACK GROWTH IN LINEAR POLYETHYLENE.** In previous investigations it has been shown that the regime of slow crack growth and the time to failure depend directly on the initial rate of crack-tip opening and damage. In this paper we demonstrate that a more appropriate fracture parameter to correlate various load levels, crack lengths, and specimen geometries under small-scale-yielding conditions is the J-integral rather than K. Since the initial rate of damage depends directly on the J-integral, the phenomenon of long-time failure by slow crack growth should be correlated by the J-integral for linear PE. (Author abstract). 14 Refs.

## Crazing

**081499 DIRECT MEASUREMENTS OF THE STRAIN ON THE BOUNDARY OF CRAZES IN POLYETHYLENE.** The strain distribution was measured on the boundary of crazes in polyethylene by a new technique where the crazes were produced under plane strain conditions. The strain distribution indicated that crazes in a linear homopolymer are weaker than those in a copolymer. The stress-strain curves of these polymers were used to obtain information about the stress field associated with the observed strain field. These results represent the first direct measurements of the strain field on the boundary of the craze without recourse to theory or arbitrary assumptions. (Author abstract) 14 refs.

**081500 MICROMECHANISMS OF DEFORMATION IN POLYETHYLENE.** It is widely accepted that crazes form in polymers on a plane which is always normal to the direction of maximum principal tensile strength. In this work both fracture surfaces and stress-whitened appearance of the shear crazes suggest that void growth occurred during their formation. A mechanism for the growth of voids in polyethylene due purely to the action of an applied shear stress is proposed. Mackerel markings on craze surfaces are discussed. It is also proposed that the polymer-substrate combinations which show good peel strength are those which can blunt the advancing peel front. 14 Refs.

**Crosslinking** See Also ELECTRIC INSULATING MATERIALS—Measurements; PIPE, PLASTIC—Manufacture.

**081501 ESTIMATION OF INTERNAL STRESSES IN ORIENTED POLYETHYLENE FILMS CROSS-LINKED BY RADIATION.** The purpose of this work is to study heat shrinkage in irradiated oriented LDPE both under isothermal conditions and during dynamic heating. An explanation of the observed effects is put forward. A correlation between the heat-shrinkage and strength properties of products fabricated from LDPE is demonstrated. It is shown that the shrinkage stresses and tensile strength increase with increase of the absorbed radiation dose in the case of 'first irradiated, then oriented' specimens, and decrease in the case of 'first oriented, then irradiated' specimens. This may be attributed to differences in the relative contents of load-holding chains. There exists for each specimen (depending on the absorbed radiation dose and on the degree of orientation) a certain critical temperature in the region of which the shrinkage stresses reach a maximum. 5 refs.

**081502 RELATIONSHIP BETWEEN DEGREE OF CROSSLINKING AND LONG-TERM STRENGTH IN POLYETHYLENE TUBES.** The specifications for manufactured crosslinked tubes are laid down in DIN 16892. According to this standard, the degree of crosslinking achieved is determined by measuring the gel fraction. There is, however, no universally valid correlation between gel fraction and long-term strength, with the consequence that different gel fractions have to be specified according to method of manufacture. This paper reports on previous studies in which long-term behavior was investigated, without specifying the degree of crosslinking. The degree of crosslinking was such that the gel fractions were fairly close to the minimum specified by DIN 16892, and in addition, when the production method allowed, about 20% above and below this level. 7 refs.

Poschet, G. *Kunstst Ger Plast* v 77 n 8 Aug 1987 p 28-31.

**081503 FLOW BEHAVIOUR OF POLYBLEND: CROSSLINKABLE POLYETHYLENE AND CROSSLINKED BUTYL RUBBER.** The rheological behavior of polymer blends consisting of crosslinkable polyethylene (XLPE) and crosslinked butyl rubber (XL-20) were studied with the help of a capillary rheometer at four shear rates and three temperatures. The viscosity of the blends increased with increasing elastomer content. The rubber microgel was broken down at high shear rate with consequent viscosity decrease which was predominant at higher XL-20 content. The flow activation energy showed inversion above 50% XLPE and decreased with the shear rate. Recoverable deformation and the Weissenberg number related linearly to the swelling ratio. The stored elastic energy and relaxation time increased with the increase in XL-20 content. Phase inversion seems to occur at the 50:50 ratio. (Author abstract) 24 refs.

**081504 POLYETHYLENE. KINETICS OF CROSSLINK FORMATION AS OBSERVED IN A SEMILO-CAL SPACE-SCALE USING NMR.** This work deals with the kinetics of gelation of high molecular weight polyethylene as it can be observed 'in situ' from the magnetic relaxation of protons attached to polymer chains. The gelation process starts from strongly entangled chains in a melt where they determine a temporary network structure. One of the features of this study is the observation of the gelation process from its effects on this network structure; in other words, crosslinks are not directly perceived from NMR because their concentration is too low. Covalent bridges induce topological constraints exerted on chain segments in addition to those created by entanglements; the kinetics of crosslink formation is detected from the progressive variation of statistical properties of chain segments defining the initial network structure. These serve as 'amplifiers' of properties at a point. 9 refs.

**081505 PEROXIDE-CATALYZED GRAFTING OF MALEIC ANHYDRIDE ONTO MOLTEN POLYETHYLENE IN THE PRESENCE OF POLAR ORGANIC COMPOUNDS.** The crosslinking of LDPE resulting from reaction with dicumyl peroxide at 180°C is increased in the presence of maleic anhydride (MAH). The presence of electron-donating nitrogen-containing compounds (amides, lactams, disubstituted aromatic amines, and amine oxides), phosphorus-containing compounds (phosphites, phosphates, phosphonates, phosphoramides, and phosphine oxides) and sulfur-containing compounds (sulfoxides, aryl disulfides, and thiazyl disulfides) which inhibit the homopolymerization of MAH but not that of methyl methacrylate, prevents crosslinking and yields soluble PE containing MAH units. (Edited author abstract) 8 refs.

**081506 TEMPERATURE-DEPENDENCE OF MECHANICAL AND MORPHOLOGICAL PROPERTIES OF ULTRA-HIGH MOLECULAR WEIGHT POLYETHYLENE CROSS-LINKED BY ELECTRON BEAM IRRADIATION.** Cross-linking of ultra-high molecular weight polyethylene was performed with electron-beam irradiation in the range of radiation dose from 12 to 96 Mrad under nitrogen. Dry gel films and melt films were used as specimens. Two kinds of cross-linked specimens could be kept at 200°C for a prolonged time in an undeformed state and this tendency was independent of radiation dose. The elongation of the gel films hampered the heat-resistant effect and the drawn specimens were broken at temperatures lower than 175°C. The elongation of the melt films could not be realized, because of a marked fixation of chains in the fiber network, even at a dose of 12 Mrad. (Author abstract) 26 refs.

**081507 UNTERSUCHUNGEN ZUR ELEKTRO-STRALH-VERNETZUNG VON PE MIT DER FT-IR-SPEKTROSKOPIE.** [Investigation of PE Crosslinking by Electron Beams Using Fourier Transform Infrared Spectroscopy]. This investigation concerned the possibility of determining the gel content of the polymers crosslinked by electron beams by means of Fourier transform infrared spectroscopy. The investigations were carried out on extruded low density polyethylene (LDPE) foils crosslinked by electron beams of different doses in air. Determination of the gel content was made by means of xylol. It was found that by using special abrasive paper linings it was possible to obtain good polymer preparation for quantitative IR spectroscopy. The absorption rate is correlative with the gel content in LDPE. 7 Refs. In German.

## Crystal Lattices

**081508 TEMPERATURE DEPENDENCE OF THE CRYSTAL LATTICE MODULUS AND THE YOUNG'S MODULUS OF POLYETHYLENE.** The temperature dependence of the crystal lattice modulus of polyethylene was measured by X-ray diffraction with use of ultradrawn films produced by gelation/crystallization from dilute solution. Measurements were carried out in the temperature range 20-150°C for specimens with draw ratios > 300. The measured crystal lattice modulus was in the range 211-222 GPa, and the values were independent of temperature. In contrast, the storage modulus of an ultradrawn film with a draw ratio of 400, 216 GPa at 20°C, decreased to 130 GPa at 140°C. This discrepancy was related to an increase in the amorphous content and a decrease of the amorphous modulus with increasing

temperature. (Author abstract) 27 refs.

Matsuo, Masaru (Nara Women's Univ, Nara, Jpn); Sawatari, Chie. *Macromolecules* v 21 n 6 Jun 1988 p 1653-1658.

**081509 MATHEMATICAL TREATMENT OF THE TEMPERATURE DEPENDENCE OF THE CRYSTAL LATTICE MODULUS AND THE YOUNG'S MODULUS OF POLYETHYLENE.** A mathematical representation based on linear elastic theory is proposed for investigating the temperature dependence of the crystal lattice modulus in the chain direction and the Young's modulus. Mathematical formulation was carried out for a composite model of crystalline and amorphous phases. This description indicates that the crystal lattice modulus and the linear thermal coefficient as measured by X-ray diffraction are different from the intrinsic crystal lattice modulus and the coefficient. The calculated results are in good agreement with the experimental results for an ultradrawn polyethylene film with a draw ratio of 400, showing that the crystal lattice modulus is independent of temperature while the Young's modulus decreases with increasing temperatures. (Author abstract) 16 refs.

## Crystalline

**081510 SMALL DEFECTS IN CRYSTALLINE POLYETHYLENE.** A family of five crystallographic defects of three classes (two dislocations, two dispirations and one disclination) which primarily involve only one polymer chain is described for polyethylene. The extra energy associated with each defect in a perfect polyethylene crystal was computed. The crystal model used consisted of a central chain containing the defect with 18 zig-zag chains in two shells around the central chain. The zig-zag chains each had 60 carbon atoms. The conformation of each defect, placed near the center of the central chain, was adjusted to minimize the sum of the interatomic interactions. A closely related procedure was used to calculate the energy per chain at boundaries where each chain contains an identical 'partial' dislocation or disclination. The characterization of these well defined defects and partial defects greatly simplifies the establishment of connections between atomic and macroscopic scale phenomena in crystalline polyethylene. (Author abstract) 19 refs.

**Crystallization** See Also POLYMERS—Crystallization; POLYMERS—Diffusion.

**081511 HIGH PRESSURE CRYSTALLIZATION OF ULTRA-HIGH MOLECULAR WEIGHT POLYETHYLENE.** The morphology of pressure-crystallized ultra-high molecular weight ( $2.5 \times 10^6$ ) polyethylene samples was studied by scanning electron microscopy. The DSC and small angle X-ray analyses were also performed. High pressure crystallization (HPC) (at a cooling rate of  $2\text{ K min}^{-1}$  from the melt at 590 MPa), of an as-polymerized powder sample gives a fibrous band morphology. Though the lamellar thickness of powder and bulk samples increases by HPC, that of the pressure-crystallized bulk is not so large, and its distribution is wide. (Edited author abstract) 19 refs.

**081512 DENSITY, ENERGY AND ENTROPY OF DEFECTS IN THE CRYSTALLINE REGIONS OF CROSSLINKED POLYETHYLENE.** By comparison of small angle X-ray scattering, thermal analytical and electron microscopic investigations, it is shown that crosslinked polyethylene crystallizes according to the usual folded chain scheme up to defect densities of 0.9% and crystallizes micellarly for higher ones. The energy needed for the insertion of a crosslink into the lattice was

estimated to be 3.3 eV, indicating a strong deterioration of the crystal. Similarly, the calculated entropy change due to crosslinks in the crystalline regions, 7 meV/K per crosslink, is rather high. This value can be explained by assuming that crosslinks are incorporated into the crystals in a variety of conformational and configurational different ways. (Author abstract) 23 refs.

Jaeger, E. (Deutsches Kunststoff-Inst, Darmstadt, West Ger); Mueller, J.; Jungnickel, B.J. *Prog Colloid Polym Sci* v 71 1985 p 145-153.

**081513 ON THE FRACTIONATION OF HOMO-POLYMERS DURING CRYSTALLIZATION FROM THE PURE MELT.** The question as to whether fractionation occurs during the crystallization of homopolymers from the pure melt has been addressed by studying linear polyethylene mixtures. Two methods were used. In one procedure, mixtures of well-defined fractions were crystallized under controlled conditions and the subsequent fusion process was analyzed. In the other procedure, a selective extraction was carried out on an isothermally crystallized polydisperse whole polymer, and the residue was analyzed by gel permeation chromatography. Both methods lead to the same conclusion, namely that during isothermal crystallization only the very low molecular weight species crystallize separately. An extreme upper limit to fractionation corresponds to  $M = 7000$ . More likely, fractionation in linear polyethylene during bulk crystallization is restricted to molecular weights of 5000 or less. (Author abstract) 21 refs.

**081514 MECHANICAL PROPERTIES OF ORIENTED CRYSTALLIZATION POLYETHYLENE.** The method of oriented crystallization has been used in recent years on the basis of flexible-chain polymers, especially polyethylene, to develop materials with high mechanical properties. To evaluate possible areas of use of these materials - such as reinforcement elements - a detailed study of the dependence of the mechanical properties of oriented polyethylene on temperature and time is carried out and measured. 7 refs.

Boiko, Yu.M. ('Norplast' Scientific-Industrial Assoc, Moscow, USSR); Gol'dman, A.Ya.; Myasnikov, G.D.; Kuznetsova, I.G.; Tarasov, A.M.; Kovriga, V.V.; Artem'ev, V.A. *Mech Compos Mater* v 23 n 2 Mar-Apr 1987 p 134-140.

**081515 MELT TRANSCRYSTALLIZATION OF POLYETHYLENE ON HIGH MODULUS POLYETHYLENE FIBERS.** A polyethylene composite was prepared and tested. It consisted of a high-density polyethylene (HDPE) matrix and uniaxial gel-spun high-modulus PE fiber. Aided by the similarity between matrix and fiber, transcrystallization of HDPE melt on the PE fiber surface was generated. Nucleating agents were not employed. The transcrystalline growth of HDPE on the PE fiber surface was found to consist of an inner and an outer zone. The inner zone, 2-3  $\mu\text{m}$  thick, is composed of HDPE crystals nucleated on the PE fiber surface. Photomicrographs showed a well-defined region on row-nucleated HDPE on the surface of PE fiber. This means the fibrils of HDPE were found to grow out from the PE fiber axis and HDPE crystallites are oriented in planes perpendicular to the PE fiber axis. The fiber in the composite induced the transcrystalline growth of HDPE on the PE fiber surface at higher temperature than on cooling the melt. (Edited author abstract) 19 refs.

**Curing** See Also ELASTOMERS—Crosslinking.

**081516 SIMULATIONS ON RADIATION-CURED POLYETHYLENE.** Simulations of the simultaneous crosslinking and chain scission reactions that are induced in bulk amorphous polyethylene by irradiation have been

implemented with a computer. A detailed study of the various defect structures in the network is reported, to show that dangling ends have the highest population among these defects, especially at higher crosslink densities. The calculated sol fractions compare very favorably with previously published experimental studies. We find that there is about 1 chain scission for every 9 crosslinked units, i.e., one scission per 4.5 crosslinks. This is fewer scissions than had previously been deduced by application of the Charlesby-Pinner method. (Author abstract) 26 refs.

## Decomposition

**081517 LITERATURE REVIEW OF THE CHEMICAL NATURE AND TOXICITY OF THE DECOMPOSITION PRODUCTS OF POLYETHYLENES.** The literature on polyethylenes has been reviewed with an emphasis on the identification of gaseous products generated under various thermal decomposition conditions and the toxicity of those products. This review is limited to publications in English through 1984. The analytical chemical studies of the thermal decomposition products generated under vacuum, inert and oxidative experimental conditions are described. In oxidative atmospheres, which most closely simulate real fire conditions, carbon monoxide (CO) was found to be the predominant toxicant. Acrolein was another toxicant often noted in these reviewed studies. Results from seven different test procedures were considered in assessing the acute inhalation toxicity of combustion products from various polyethylene formulations. (Edited author abstract) 59 refs.

Paabo, Maya (NBS, Gaithersburg, MD, USA); Levin, Barbara C. *Fire Mater* v 11 n 2 Jun 1987 p 55-70.

## Deformation

**081518 INVESTIGATION OF THE DEFORMATION AND RELAXATION OF VARIOUS POLYETHYLENES BY X-RAY DIFFRACTION.** Three different PE samples (linear, branched, very high molecular weight) are investigated for different draw ratios (uniaxial deformation) by wide and small angle X-ray diffraction. Crystallite sizes and lattice distortions show qualitatively the same behaviour, but quantitative differences occur. There is a remarkable difference in the superstructure between 'normal' and very high molecular weight samples. The relaxation at different temperatures is investigated for linear PE. The degree of rebuilding of the original structure depends on the draw ratio and relaxation temperature (by fixed relaxation time). The results are discussed within the framework of dislocation concepts. (Author abstract) 25 refs.

Reck, E.-M. (Univ Ulm, Ulm, West Ger); Schenk, H.; Wilke, W. *Prog Colloid Polym Sci* v 71 1985 p 154-163.

**081519 ORIENTATION IN LOW-DENSITY POLYETHYLENE DUE TO AN ELEMENTARY SLIP PROCESS.** A simple, physical model has been developed to describe orientation in thermoplastic polymers, involving the boundary slip and rotation of rod-like structural elements. Orientation parameters have been calculated, and expressions for the birefringence and elastic mechanical anisotropy deduced. Results on cold-drawn, low-density polyethylene agree well with this model. (Author abstract) 12 refs.

## Degradation

**081520 PHOTO-OXIDATIVE DEGRADATION OF POLYETHYLENE: EFFECT OF POLYMER CHARACTERISTICS ON CHEMICAL CHANGES AND MECHANICAL PROPERTIES. PART I - QUENCHED POLYETHYLENE.** Photo-oxidative degradation of quenched samples of linear low density (LLD),

medium density (MD) and two kinds of high density (HD) polyethylene (PE) films was studied using a medium-pressure mercury lamp. Greater amounts of crosslinking and build up of oxidation products were noticed in LDPE than the other samples. The primary products of interaction between dienes and oxygen are considered to participate in the initiation of the photo-oxidation reactions. Using the FT-IR difference spectrum technique, the amount of branch concentration in the photo-irradiation PE samples was determined. Oxidation damage at the boundary region between crystalline and amorphous phases is considered to be important in determining the embrittlement time. (Author abstract) 21 refs.

Geetha, R. (Nagoya Univ, Nagoya, Jpn); Torikai, A.; Nagaya, S.; Fueki, K. *Polym Degradation Stab* v 19 n 3 1987 p 279-292.

**081521 DEGRADATION OF HDPE AND LDPE IN CLOSED MIXING CHAMBER: A COMPARISON. I. CHANGES IN THE CHEMICAL STRUCTURE.** Degradation of linear high density polyethylene (HDPE) and butyl branched linear low density polyethylene (LLDPE) was studied during molding in a closed mixing chamber. At the beginning of the process the rate of oxidative degradation was found faster for LLDPE than for HDPE but later this relation reversed. The degradation mechanism was the same for both types of polyethylenes but the rate of elementary steps depended on the chemical structure of the polymer chain. The differences were attributed to the structural differences in the original materials and the products formed during degradation. (Author abstract) 30 refs.

Foldes, E. (Hungarian Acad of Sciences, Budapest, Hung); Iring, M.; Tudos, F. *Polym Bull (Berlin)* v 18 n 6 Dec 1987 p 525-532.

**081522 PHOTSENSITIZING ACTION OF COMPLEX COMPOUNDS OF TRANSITION-METAL SALTS WITH AROMATIC NITROGEN CONTAINING VINYL MONOMERS.** Production of photosensitizers for degradation of high-pressure polyethylene (HPPE) and its technological wastes is of great importance for solving the problem of development of polymers having controllable life. In order to extend the range of photosensitizing additives for degradation of HPPE, we have studied aromatic nitrogen-containing vinyl monomers and their complexes with iron and cobalt chlorides. It was found that an iron-containing complex compound of the quinoline series has higher photosensitizing activity than the corresponding cobalt complex. 8 refs.

Garashchenko, Z.M. (Acad of Sciences of the USSR, USSR); Borodulina, M.Z.; Skvortsova, G.G.; Domnina, E.S.; Andriyankov, M.A.; Loginova, V.P.; Zelenkova, T.N. *J Appl Chem USSR* v 60 n 3 pt 2 Mar 1987 p 607-609.

**081523 THREE STAGES IN DEGRADATION OF POLYMERS - POLYETHYLENE AS A MODEL SUBSTANCE.** Data relating to the degradative conversion of  $^{14}\text{C}$  present in low density polyethylene (LDPE) film to respiratory  $^{14}\text{CO}_2$  during a 10-year aerated cultivation with soil are presented. The degradation was performed with two sets of LDPE samples, one without additive (PE) and the other containing UV sensitizer (NDPE). Samples were exposed to UV irradiation for 0, 7, 26, and 42 days. The degradation is characterized by three stages: (I) a constant degradation rate, (II) a parabolic decline in the rate of degradation, and (III) a subsequent final increase in the rate of degradation. (Edited author abstract) 19 refs.

Albertsson, Ann-Christine (Royal Inst of Technology, Stockholm, Swed); Karlsson, Sigbritt. *J Appl Polym Sci* v 35 n 5 Apr 1988 p 1289-1302.

**081524 TERMOOKSIDACIJSKA RAZGRADNJA POLIETILENA NISKE GUSTOCE.** [Thermooxidative Decomposition of Low-Density Polyethylene]. Several procedures for the preparation of polyethylene waxes of controlled molecular mass by thermooxidation are described. The degradation was performed in melt, in a

torsional rheometer at  $150^\circ\text{C}$ , in dichlorobenzene solution at  $130\text{--}150^\circ\text{C}$ , in a mixture of low molecular mass which appears as a by-product of free radical high-pressure polymerization of ethylene, and in aqueous dispersion under the prepressure of 1 MPa. Oxidation was performed with air or in a stream of oxygen. Due to the limited contact with oxygen, the thermooxidation of LDPE in melt is accompanied by crosslinking. Oxidation in solution enables a good contact between LDPE and oxygen, so that oxidative degradation takes place without crosslinking. However, at a high level of oxidation, the recombination of reactive low molecular mass fragments occurs, yielding products of a high molecular mass. (Edited author abstract). In Serbo-Croatian.

Jerman, Marija Biserka (INA-Razvoj i Istrazivanje, Zagreb, Yugosl); Fles, Dragutin. *Polimeri (Zagreb)* v 8 n 3 Mar 1988 p 55-57.

**081525 OXIDATIVE DEGRADATION OF POLYETHYLENE IN THE PRESENCE OF PHASE TRANSFER CATALYST: PART 1 - INFRARED STUDIES.** Oxidative degradation of polyethylene has been carried out with phase transferred permanganate as oxidant. The degradation products have been characterized by infrared spectroscopy in an attempt to elucidate the probable degradation mechanism. The oxidized polyethylenes are found to possess carbonyl, ether, hydroperoxy and several types of olefinic groups. Using FT-IR spectra, the quantitative determination of the different functional groups has also been carried out. While the initiation and termination steps are common to all PTC oxidations of low density polyethylene, the propagation in the tetrabutyl ammonium bromide (TBAB)-catalysed process occurs through intramolecular hydrogen abstraction and chain scission. (Author abstract). 19 Refs.

Konar, J. (Indian Inst of Technology, Kharagpur, India); Ghosh, R. *Polym Degradation Stab* v 21 n 3 1988 p 263-275.

**081526 DEGRADATION OF DIELECTRIC PROPERTIES OF POLYETHYLENE BY COMBINED  $\gamma$ -IRRADIATION AND THERMAL STRESSES.** Degradation of dielectric properties polyethylene under the combined environment of  $\gamma$ -irradiation and thermal aging was studied. To exclude the effect of additive agents and to minimize the effect of the process limited by diffusion of oxygen on the degradation, a 25- $\mu\text{m}$ -thick low-density polyethylene film, free from additives, was used. Dielectric relaxation was used as a tool to study the oxidative degradation. It was found that the primary dispersion of polyethylene shifts to higher temperatures with oxidation. There is some difference in temperature of primary dispersion according to the order of application of thermal aging and  $\gamma$ -irradiation. The reason for it is explained in terms of chain scission, cross linking and dipole-dipole interaction. 15 refs.

## Dielectric Properties

**081527 TEMPERATURE EFFECTS IN CRYSTALLINE POLYETHYLENES DIELECTRIC RELAXATION.** Recently we proposed a soliton model for the crystalline  $\alpha$ -relaxation in polyethylene. The continuum limit theory accounted reasonably well for the observed dielectric data at low temperatures, but failed to explain the change in the shape of the Cole-Cole plots (increase in the Cole-Cole width parameter  $\beta$ ) with temperature. We extend the theory by considering the effects of both conformational defects and soliton interactions. In the defect barrier model the conformational defects are modelled as infinite reflecting or absorbing barriers to soliton motion. This results in a  $\beta = 0.48$  Williams-Watts dielectric decay function not significantly different from the defect-free result, which predicts no change in the shape of the Cole-Cole plot with temperature. (Edited author abstract) 29 refs.

**081528 INFLUENCE DES METHODES DE MISE EN OEUVRE DU POLYETHYLENE (PEBD) SUR SON COMPORTEMENT SOUS HAUTE TENSION CONTINUE.** [Influence of the Manufacturing Process of LDPE on its Behaviour under Electric Stress]. In order to improve the insulating properties of low density polyethylene (LDPE) under electric stress, a systematic study of LDPE based materials has been conducted. This investigation has been made by measuring, using the pressure wave propagation method, the evolution of charge or dipole distributions in samples submitted to a high voltage gradient. Two "pure" LDPE resins of different origins were used to prepare planar geometry samples, identical in any other respects. The behaviour of these samples is compared, for various applied fields, temperatures and chemical formulation of the electrodes. From these results, new informations relative to charge storage and transport in these materials are obtained. It is shown that, by studying directly the influence of the chemical composition of materials on their electrical properties, it will be possible to define highly performing insulations. (Author abstract). 8 Refs. In French.

**081529 ETUDE COMPARATIVE DU COMPORTEMENT SOUS TENSION CONTINUE, DE DEUX TYPES DE POLYETHYLENE PAR LA METHODE DE L'ONDE DE PRESSION.** [Comparative Study of the Behavior of Two Polyethylene Types under DC Voltage, by the Pressure Wave Method]. In order to develop extruded DC high voltage cables, it is necessary to improve the understanding of charge storage and transport phenomena occurring in insulants such as polymer materials, when they are submitted to high DC voltages. A comparison of the behaviour of two types of polyethylene, LDPE and XLPE, is presented. This study is based on the measurement, using the pressure wave propagation method, of the evolution of charge distributions in samples under electric stress. Important characteristics of these two materials are obtained, such as the internal field distribution, its distortion as compared to the applied field, and the localization of the charges responsible of these effects. For the materials under test, some regions of the samples are submitted to a field exceeding the applied one by 80%. Nevertheless the localization of the space charges observed in some situations indicates that there is no particular risk during a reversal of the polarity of the applied voltage. (Author abstract). 5 Refs. In French.

## Doping

**081530 CONNECTIVITY OF CONDUCTING CRYSTALLINE NETWORKS IN RETICULATE DOPED POLYMERS.** Measurements of temperature dependences of conductivity for morphologically different samples of reticulate doped polymers containing dendrite-like microcrystals of a conducting charge-transfer (CT) complex demonstrate that there is no difference in the mechanism of charge carrier transport along dendrite branches, perpendicular to them or across interdendrite boundaries. Comparison of the conductivity behavior, as measured along polymer films and perpendicular to the surfaces ('sandwich' samples), suggests that the same mechanism of conductivity operates in both directions. It is also demonstrated that lowering of the CT complex content, even to 0.003 vol. fraction, leads to some decrease of the conductivity but does not change its temperature dependence. The results demonstrate the high connectivity of the crystalline CT complex network and support the hypothesis that continuity of this network is due to submicroscopic dendritic structures scaling from microns,

probably down to tens of angstroms. (Author abstract) 15 refs.

#### Elasticity

**081532 ELASTIC MODULUS OF POLY(ETHYLENE TEREPHTHALATE-CO-P-OXYBENZOATE).** The article concerns a polyethylene terephthalate modified by p-hydroxybenzoic acid (PET/PHB 60). The authors determined the mechanical properties of fibres of PET/PHB 60 spun at 260°C. The high modulus found is related to the high level of orientation obtained from the large values of the order parameters calculated from X-ray diffraction patterns. Higher values of orientation and elastic modulus can be obtained if one prevents the loss of orientation reached during processing. This can be attained by positioning the takeup machine as close as possible to the spinneret. 14 Refs.

#### Electric Breakdown

**081533 SIMULTANEOUS MEASUREMENT OF MICROSCOPIC IMAGE AND DISCHARGE PULSES AT THE MOMENT OF ELECTRICAL TREE INITIATION.** This paper reports some experimental results concerning the tree initiation from a semiconductive needle electrode in polyethylene under a 50 Hz AC voltage. With a newly developed measuring system, the correspondence between partial discharge pulses and tree initiation and growth up to 10-20 µm in length was clarified for the first time. Tree observation and pulse measurement were made simultaneously. At the moment of tree initiation, positive pulses (current from the needle towards the grounding electrode) of 0.05-0.1 pC were first observed. A very small shade of the initial tree was observed when continuous positive pulses appeared; it grew rapidly to about 10 µm in length, along with the positive and negative pulses. After the tree branched, the growth rate dropped for a while. In many cases, the negative pulses disappeared during this stage. (Author abstract) 4 refs.

#### Electric Conductivity

**081535 SIMULTANEOUS THERMALLY STIMULATED LUMINESCENCE AND CONDUCTIVITY IN LOW-DENSITY POLYETHYLENE.** Thermally stimulated luminescence (TSL) and conductivity (TSC) in low-density polyethylene samples were measured simultaneously, while the sample was being heated to room temperature after x-ray irradiation at -190°C. The TSC curves of samples from which absorbed air had been removed showed five peaks, labelled C<sub>1</sub>-C<sub>5</sub> in order of increasing temperature, while the TSL glow curves showed only three peaks (L<sub>1</sub>-L<sub>3</sub>). The effects of these peaks of (i) immersing the samples in fuming nitric acid, (ii) annealing them in vacuum, and (iii) exposing them to an oxygen/ozone mixture, were investigated. When the samples contain absorber air, a hitherto unreported peak is observed in the TSC curve, corresponding to the TSL 'gas' peak. (Edited author abstract) 23 refs.

**081537 THERMALLY STIMULATED CURRENT MEASUREMENT IN HIGHLY ELONGATED POLYETHYLENE FILM.** The trap depth and density in highly elongated polyethylene have been studied by thermally stimulated current (TSC) measurements. Three discrete traps with depths of 0.13, 0.3 and 0.5 eV have been evaluated using the initial rise method in the temperature region from 77 to 330 K; these change slightly with the elongation ratio. A trap density of the order of 10<sup>13</sup> approx. 10<sup>14</sup>/cm<sup>3</sup> has been calculated from the area of the TSC peaks. The trap density increases upon increasing the elongation ratio and again decreases at a higher elongation ratio; this is consistent with the elongation dependence of the electric conductivity and carrier mobility. The results are discussed in terms of the molecular orientation examined by X-ray diffraction measurements. (Edited author abstract) 10 refs.

**081538 INFLUENCE OF WALL SLIP ON EXTRUDATE SWELL: A BOUNDARY ELEMENT INVESTIGATION.** This paper reports a numerical study of the extrudate swell by a transient Boundary Element Method (BEM). Furthermore the fluid, which is modeled by a differential constitutive equation, is allowed to slip at the wall, where the slip velocity is a prescribed function of the wall shear stress. This function is a curve fit of the extensive data of A.V. Ramamurthy on linear low density polyethylene which incorporates two parameters: a critical

wall shear stress above which slip occurs, and another parameter which governs the shape of the slip velocity versus shear stress curve. The results show that wall slip reduces both the amount of extrudate swell and the critical Weissenberg number above which our numerical scheme no longer converges. (Author abstract) 15 refs.

Phan-Thien, N. (Univ of Sydney, Aust). *J Non Newtonian Fluid Mech* v 26 n 3 Jan 1988 p 327-340.

**081539 INFLUENCE OF SCREW CLEARANCE ON PROCESSING PARAMETERS FOR SINGLE-SCREW PLASTICISING EXTRUDERS.** When LLDPE was processed on an air-cooled, single-screw extruder, an increase in the screw clearance  $\delta$  led, contrary to expectations, to a clear rise in the mean melt temperature and to a slight increase in the specific mechanical energy consumption. The mechanical and thermal homogeneity of the melt that was produced, the axial pressure profile and also the torque and the melt throughput are scarcely influenced by the amount of screw clearance. When a high-molecular HDPE, highly susceptible to wall slippage was processed, screw clearance was seen not to have any notable influence on the process parameters under investigation. The results are explained by wall slip effects and by heat and material transport phenomena in the gap region. (Author abstract) 15 refs. In German and English.

Gruenschloss, E. *Kunstst Ger Plast* v 77 n 9 Sep 1987 p 29-31.

**081540 CORRELATION OF THE PROCESSING PARAMETERS AND THE PHYSICAL-MECHANICAL PROPERTIES OF ARTICLES IN EXTRUSION OF POLYETHYLENE.** Regression equations which correlate the technological parameters of processing of the polymer with the deformation-strength properties of extruded polyethylene were obtained. It was found that the brand of raw material has a very large effect on  $\sigma$ , which is in agreement with the a priori data. These brands probably have different molecular-weight distribution. Significant effects of paired interactions of the factors were observed in the determination of  $\epsilon$ . Information was also obtained on the character of the change in the molecular structure of the industrial brands of PE used during extrusion, and the role of the factors which influence these changes was also examined. 5 refs.

**081541 DIE SWELL-MOLECULAR STRUCTURE MODEL FOR LINEAR POLYETHYLENE.** An empirical relation between capillary die swell and molecular structure, defined by total weight average molecular weight, molecular weight distribution (MWD), and fraction high molecular weight content is established. Via a Box-Behnken experimental design setup blends of Ziegler-Natta catalyzed linear polyethylenes are prepared to allow a statistical analysis of the die swell-molecular structure relation. The contradicting results of M.G. Rogers and R.A. Mendelsen et al. for the die swell-molecular structure relation are shown to be compatible and are to be considered as special cases of the general model presented. The existence of a die swell maximum is shown. (Edited author abstract) 26 refs.

#### Failure

**081542 INFLUENCE OF THE MOLECULAR WEIGHT OF LOW DENSITY POLY(ETHYLENE) ON WATER TREING IN RELATION TO MECHANICAL DAMAGING.** The influence of the molecular weight of low density poly(ethylene) on the propagation of water trees is studied and compared with environmental stress cracking data. Water treing is interpreted as a mechanical damaging of the polymer due to the action of local stresses of electrical origin. The propagation of water trees is discussed in terms of plastic deformations of

the amorphous inter- or intraspherulitic spaces, induced by stretching action of dynamic forces of electrical origin on the tie molecules. (Author abstract) 8 refs.

**Fiber Reinforcement** See PLASTICS, REINFORCED—Electric Conductivity.

## Filaments

**081543 INFLUENCE OF SURFACE TREATMENT ON ADHESION OF POLYETHYLENE FIBRES.** A detailed examination has been undertaken of the influence of surface treatment on the adhesion of polyethylene fibres to epoxy resin. The pull-out adhesion has been determined for untreated, chromic acid treated, and plasma etched monofilaments with different draw ratios and thermal annealing treatments. In a few cases, additional chemical treatments were applied to plasma treated fibres before the pull-out test. The polyethylene surface energy also has been determined by measurement of contact angle. The results, taken together, suggest that the adhesion depends on three factors: (i) the wettability (or physicochemical interactions), which is affected by the extent and nature of the surface treatment as well as the fibre draw ratio; (ii) the surface roughness, after plasma etching only, where a honeycomb structure of pits permits mechanical keying between the fibre and the resin (this structure has been examined by scanning electron microscopy); and (iii) the number of chemical bonds per unit area between the fibre and the resin. It is concluded that these three factors can be regarded as additive and that optimum results are obtained when their respective pull-out strengths reach their maximum values, approximately 2, approximately 3, and approximately  $1.7 \text{ MN m}^{-2}$ . (Author abstract) 21 refs.

**081544 PORE FIBERS OF POLYETHYLENE OBTAINED BY SPINNING AND CRYSTALLIZATION FROM ORIENTED MELT OF MIXTURES WITH PARAFFIN.** A method for the preparation of pores in high molecular weight polyethylene (PE) fibers was examined. Mixtures of PE and liquid paraffin (Pa) with various composition ratios were spun from the melt at various temperatures and rates, and then PE was extracted in organic solvent. The fine structure of these pores in PE fiber was investigated through the measurements of apparent specific volumes, specific surface areas and small angle X-ray scattering. Layer-like pores were formed under the conditions of a mixing ratio of PE and Pa in the range of 0.10 to 0.50 at a spinning draft ratio 6 to 50 times at 110 to 125°C. (Edited author abstract) In Japanese. 13 refs.

**081545 DIRECT ELECTRON MICROSCOPE INVESTIGATION OF THE MORPHOLOGY OF SURFACE-GROWN POLYETHYLENE FILAMENTS BEFORE AND AFTER ZONE-DRAWING.** The supermolecular structure of surface-grown and surface-grown/hot-drawn PE has been the subject of numerous detailed studies. However, a clear characterization of the different morphologies has not so far been achieved. The present TEM study is to provide convincing evidence of the microfibrillar structure of as-spun surface-grown fibers and of morphological changes fibers experience during high-temperature zone drawing. Under these conditions of fiber spinning and drawing, large-scale disturbed regions within the fiber structure may arise, such as kink bands, agglomerations of fibril ends, or boundary layers of longitudinal voids which separate fibrillar aggregates laterally. 21 refs.

**081546 INFLUENCE OF MIXED FILLERS ON THE RESISTANCE TO EXTRUSION OF MOLTEN POLYMERS THROUGH NOZZLES AND ON THE SMOOTHNESS OF THE EXTRUDATE SURFACE.** The objective of the present work was to establish the effect of the concentration and composition of a combined filler, consisting of a mixture of different dispersed particles, on the viscosity and strength of the melt in the case of shear flow at shear rates close to those used in actual processing. The addition to the molten polymer of a filler of spherical shape, which is not inclined to agglomeration and aggregation of the particles (for instance, glass spheres or steel balls), increases the viscosity of the compositions only slightly, particularly in the region of high shear rates. The combined fillers used were mixtures of glass spheres with chalk or limestone powder. 11 refs.

**081549 EFFECT OF ENTANGLEMENTS ON THE SUPER STRUCTURE GENERATED BY DRAWING GEL PROCESSED FILMS OF ULTRA-HIGH MOLECULAR WEIGHT POLYETHYLENE.** The super-drawn structure of gel processed films of ultrahigh molecular weight polyethylene was studied by these methods: differential scanning calorimetry (DSC) in relation to the elastic property, the morphology after melting, and the wide angle X-ray diffraction at high temperature. Two kinds of endothermic peaks were observed, around 153°C and above 160°C, in the DSC curves of fixed-end films. The lower temperature peak includes the heat of fusion of orthorhombic crystallites and the heat of transition from the orthorhombic to hexagonal phases. The higher temperature peak corresponds to the melt of hexagonal parts. (Edited author abstract). In Japanese. 20 refs.

**081550 APPLICATION OF  $\text{C}_8$  LLDPE IN FLEXIBLE PACKAGING.** An extensive market survey indicated that the qualities of packaging films needed to be improved regarding easier and more reliable film sealing properties and better puncture resistance. To meet these requirements a new range of very low density (below  $918 \text{ kg m}^{-3}$ )  $\text{C}_8$  linear polyethylenes (Stamylux) LLDPE was developed. Linear low density PE has a linear molecular structure with short chain branches. It is a copolymer with a higher  $\alpha$ -olefin as comonomer. It has a narrow molecular weight distribution (MWD). LLDPE has a molecular structure with both short and long chain branches. It is a homopolymer with a broad MWD. (Edited author abstract)

**081551 LLDPE AND UV AGEING.** This paper deals with the ultra-violet (UV) ageing of low linear density polyethylene (LLDPE) films with an without UV stabilizer. Pure LLDPE and LLDPE, and blends of these two materials have been compared by outdoor exposure or artificial ageing in a Xenotest 150. Parameters influencing the lifetime of LLDPE films have been examined, such as film thickness, melt index and catalyst residue level of LLDPE, nature of the comonomer (butene-1,4-methylpentene-1, hexene-1), and backing during outdoor exposure. (Edited author abstract)

Cordonnier, Michel (Usine de Lavera, Lavera, Fr). *Plast Rubber Process Appl* v 8 n 1 1987 p 23-27.

**081552 EFFECT OF PROCESSING CONDITIONS ON THE MICROSTRUCTURE OF EMBOSSED POLYETHYLENE FILMS.** A variety of techniques were employed to characterize the properties and microstructure of the embossed film in relation to: crystallinity, orientation, mechanical properties, and dimensions of the embossed films. The thermal treatment of the polymer film was shown to be the most significant factor in the process. By controlling the thermal treatment of the film, it is possible to manipulate the properties and dimensions of the embossed film. The important aspects influencing thermal treatment include the radiation heater temperature, preheat roll temperature, line velocity, and film thickness. The initial film orientation and embossing pressure have a minor effect on the final properties of the embossed film. The main effect of the embossing pressure is on the bulk thickness of the embossed film. (Edited author abstract) 8 refs.

**081554 SHRINKAGE OF LOW-DENSITY POLYETHYLENE FILM.** When blown films of low-density polyethylene are heated above their melting point ( $T_m$ ) they shrink to an unoriented state at a conveniently measurable rate. Curves of contraction as a function of time have been measured at different temperatures ranging

from 120°C to 200°C. The contraction curves for shrinkage in the machine direction obtained at different temperatures are superimposable by a lateral shift along the log-time axis. A master contraction curve, a portion of the retardation spectrum, and the activation energy are obtained. Shrinkage data for low-density polyethylene films with different thicknesses were analyzed and a correlation was found between contraction and dichroic ratio. The correlation indicates that thermal contraction data can be used as a qualitative measurement of orientation in low-density polyethylene film. (Author abstract) 12 refs.

Fracture See Also PIPE, PLASTIC—Testing.

**081555 EFFECTS OF DETERGENT CONCENTRATION AND ETHYLENE OXIDE CHAIN LENGTH OF THE DETERGENT MOLECULE ON STRESS-CRACKING OF LOW-DENSITY POLYETHYLENE.** Stress-cracking behavior of low-density polyethylene is investigated using a fracture mechanics approach. It is experimentally observed that  $K_{Ic}$  independent crack speed is directly proportional to the concentration of Igepal CO-630 up to 25% concentration.  $K_{Isc}$  is found to increase with detergent concentration; and the increase in  $K_{Isc}$  is attributed to the larger amounts of detergent absorption in the higher concentrations, which decreases the strain localization at the crack tip. Micelle formation of detergents in water is thought to enhance the rate of cracking because of their ability to increase plasticization efficiency at the local area because the micelles contain larger amounts of aggressive molecules. In contrast to Williams' model, the cracking behavior in the constant crack speed region is found to be not controlled by the flow properties of the environment. (Author abstract) 16 refs.

**081556 SLOW FRACTURE IN A HOMOPOLYMER AND COPOLYMER OF POLYETHYLENE.** The slow crack growth behaviours of a high-density polyethylene and an ethylene-hexene copolymer with 4.5 butyl chains per 1000 carbon atoms are compared. The slow crack growth rate in the copolymer is about  $10^2$  to  $10^3$  times slower than that for the homopolymer. The two polymers are compared with respect to their kinetics of crack growth, morphology of the damage zone that grows from a notch, stress-strain behaviour and temperature dependence of the rate of damage. The results suggest that the major effect of the butyl branches is to decrease the rate of disentanglement which governs the process of slow crack growth. (Author abstract) 11 refs.

**081558 ORIENTATION DISTRIBUTION FUNCTION IN CRYSTALLITES OF ROLLED HIGH DENSITY POLYETHYLENE FILMS.** An evaluation method of the crystalline orientation distribution function is proposed, based on the model that the lamella axis is one of the principal axes in the crystalline block and that the slippages are introduced along the maximum shear direction and the intra-lamella slip around the  $0-x_2$  axis. This method was applied to rolled high density polyethylene film, and the results compared with observed pole figures. Expansion coefficients as far as the 8th were employed for the elevation of pole figure calculation. (Edited author abstract) In Japanese. 11 refs.

**081559 RE-ORIENTATION OF MOLECULAR CHAIN AXIS AND BEHAVIORS OF PLASTIC DEFORMATION IN THE OFF-ANGLE RE-STRETCHING OF ROLLED HIGH DENSITY POLYETHYLENE.** The mechanisms of plastic deformations were further investigated in connection with the re-oriented molecular chain axis in the off-angle re-stretching of the rolled high density polyethylene (RHPE). The slippery or kinky deformation caused by off-angle re-stretching was analyzed on the basis of the strain ellipsoid, molecular chain vectors and a local coordinate system. The deformation is caused by the slip of inter- and intra-lamella. The molecular chain axis can be easily re-oriented in the film by a pure shear stress which is much larger than the simple shear stress. The kink band formation markedly promotes the re-orientation of the molecular chain axis. (Author abstract) 16 refs. In Japanese.

**081560 ANALYSES OF DEFORMATION BAND WITH CHARACTERISTIC CURVES AND RE-ORIENTATION BEHAVIORS OF MOLECULAR CHAIN AXIS WITH THE MODEL OF PLASTIC SLIPPAGE.** The authors analyzed the re-orientation angle of molecular chain axes in the plastic deformation and the angles of kink band in the off-angle re-stretching of rolled high density polyethylene (RHPE). The authors evaluated the kink band angles using the characteristic curves. As the strain yield points in polymers became much greater than those of the metals, the change of orientation angles must be corrected due to elasto-plastic deformation. The re-orientation mechanisms of the chain axis during the off-angle stretching may be divided into the slipping and kinky deformations. These were given by the slippage of the inter-lamella and by the chain slip in the intra-lamella, respectively. The orientation of the molecular chain axis in the chain slip was much greater than that of the inter-lamella slip. (Author abstract) 17 refs. In Japanese.

**081561 SYNERGISM OF ANTIOXIDANTS IN HIGH DENSITY POLYETHYLENE.** The effect of several commercial antioxidants (viz. phosphites and hindered phenols) used in synergistic formulations in two grades of high density polyethylene (HDPE) has been examined using infra-red (ir) spectroscopy. The results show that, in general and, as expected, synergism is obtained between hindered phenols and phosphites in HDPE films during oven aging and uv irradiation condi-

tions. However, the degree of synergism is not the same for both grades of HDPE, which differ mainly in their unsaturation and metal impurity content. In some cases, antagonism is observed in one of the HDPE samples while synergism is exhibited by the other. There is also a difference regarding the optimum concentration ratio of the antioxidants in each polymer. Formulations which include a commercial metal deactivator (Nauard XL 1) also show synergistic behavior. The reasons for the observed behavior are discussed on the basis of the mode of action of the antioxidants and their rate of consumption in the polymer medium. (Edited author abstract) 7 refs.

**081562 HIGH-DENSITY POLYETHYLENE (HDPE).** To assess the market situation and its development, Western Europe (WE) must be looked at as a unit. After the persistent recession of 1980 to 1982, there was a sudden improvement in 1983, and between 1984 and 1986 consumption increased some 28%. (HDPE production over the same period rose only about 18%. At present there are 16 producers of HDPE in Western Europe. In the percentage breakdown on HDPE consumption into the individual processing areas the blow moulding and injection moulding are still the most important sectors. In quantity terms they have lost market share. The film sector is still recording powerful growth in proportionate and absolute terms. Continuous growth is perceived for pipe and sheet. Usage of tapes and monofilms is developing at an average rate: their share of the HDPE market as a whole has scarcely altered for several years. HDPE is produced by suspension, solution, and gas-phase processes with Ziegler or Phillips catalysts. Specially tailored catalysts have been developed for this purpose, which make it possible to produce a specific molecular weight distribution in one simple process. 7 refs.

**081563 INFRA-RED STUDY OF BOND RUPTURE DURING PLASTIC DEFORMATION IN HIGH-DENSITY POLYETHYLENE.** The effects of elongation, time and temperature upon the concentrations of carbonyl and vinyl groups formed during the plastic deformation of high-density polyethylene have been studied using infra-red spectroscopy. Samples drawn in various atmospheres are also described. The morphology of lamellar crystallized polymers is now taken to involve both folded chains and those linking adjacent lamellar cores. We propose an alternative explanation for the processes that occur when spherulitic materials become oriented and fibrillar. We propose and provide evidence that mechanical work is concentrated into very small volumes in the neck region leading to localized melting and subsequent recrystallization. (Edited author abstract)

**081564 ORIENTATION DISTRIBUTION FUNCTIONS OF OFF-ANGLE REDRAWING IN ROLLED HIGH DENSITY POLYETHYLENE FILMS, CALCULATED WITH THE PLASTIC SLIP MODEL.** We evaluated the orientation distribution functions of each plane normal for off-angle re-drawing in rolled high density polyethylene films. The pole figures' device familiar in X-ray diffraction was used. These distribution functions were compared with the schematic simulation of orientation in crystallites after such re-drawing, by assuming polycrystalline aggregations. We analyzed the mechanism of re-orientation for a re-drawing process in which

the [110], <001> slip system dominated in three types of chain slip systems by the maximum work principle. (Author abstract). 12 Refs. In Japanese.

**081565 HDPE RECYCLE: IT'S A BIG-VOLUME OPPORTUNITY WAITING TO HAPPEN.** A mere 2.4 percent of 3.3 billion lb of amenable blow and injection molded rigid containers was recycled last year; and the price of virgin high density polyethylene (HDPE) blow molding has risen by 70 percent since early 1987. As a result, HDPE containers have emerged as the most promising candidate for recycling especially since they are easily identifiable. The best strategy for the re-use of HDPE appears to be in the area of nonfood applications, such as pipes, flower pots, and plastic lumber.

## Ion Implantation

**081567 CHEMICAL CHANGES CREATED BY HIGH ENERGY IONS IN POLYETHYLENE.** Argon and oxygen ions were accelerated with energies of 50 to 150 keV and rastered across high-density polyethylene. The free radicals formed in the ion-implanted polyethylene were studied using an electron spin resonance spectrometer. The free radicals formed were stable in air and even survived solvent separation of the undamaged polymer from the ion-damaged polymer. Chemical characterizations indicated that pregraphitic or graphitic-like particles are formed with defect sites which are, in effect, free radicals stabilized by a polyaromatic system. 48 refs.

## Ionization

**081568 WETTING OF FUNCTIONALIZED POLYETHYLENE FILM HAVING IONIZABLE ORGANIC ACIDS AND BASES AT THE POLYMER-WATER INTERFACE: RELATIONS BETWEEN FUNCTIONAL GROUP POLARITY, EXTENT OF IONIZATION, AND CONTACT ANGLE WITH WATER.** This paper examines the wetting by water of low-density polyethylene film modified at the polymer-water (air) interface by introduction of polar organic functional groups (carboxylic acids, amines, and others). Water/polymer contact angles were determined for each of these interfaces; for interfaces containing acidic or basic functional groups, the contact angle was determined as a function of the pH. The observed contact angle was related to the hydrophilicity of these functional groups: as the hydrophilicity (as measured by Hansch  $\pi$  parameters) increased up to a certain point, the contact angle decreased. Beyond that point, increased hydrophilicity had

little additional influence on the contact angle. The paper rationalizes the change in contact angle with pH in terms of the relative areas of the interface occupied by the functional groups in different ionization states and in terms of the extent of ionization of acidic and basic groups. (Edited author abstract). 39 Refs.

**081570 FRACTIONATION AND THERMAL BEHAVIOUR OF LINEAR LOW DENSITY POLYETHYLENE.** An ethylene/1-octene copolymer has been fractionated by molecular weight using successive solution fractionation (s.f.f.). The fractions obtained and the original copolymer were analysed with respect to the short chain branching distribution using analytical temperature rising elution fractionation (a.t.r.e.f.). A bimodal, very wide branching distribution is observed, both for the non-fractionated polymer and for the s.f.f. fractions. A decrease of the average degree of branching with increasing average molecular weight of the fractions is observed. The melting behaviour of isothermally crystallized samples was studied using differential scanning calorimetry (d.s.c.). (Edited author abstract) 12 refs.

**081571 MECHANICAL BEHAVIOUR OF LINEAR LOW DENSITY POLYETHYLENE FIBRES.** The mechanical behavior of linear low density polyethylene fibers has been investigated by means of uniaxial elongation tests and thermomechanical measurements. A mechanical model initially introduced by for HDPE fibers is proposed to account for the experimental results. In this model based on the crystalline continuity, it is interrupted by adjunction of a small fraction of amorphous phase in series with the mechanically active crystals. This fraction is determined by means of an original theoretical treatment of the stress-strain curves of the fibers. Correlations have been set up between this additional parameter and the mechanical properties of the fibers. (Edited author abstract) 23 refs.

**081572 LES PROGRES EN POLYETHYLENE BASSE DENSITE LINEAIRE POUR FILM. [Progress in Linear Low Density Polyethylene for Films].** LLDPE continues to progress in Western Europe. Its percent of the film market has increased from 5% in 1983 to 12% in 1986. LLDPE is mainly used for films, and progression in this market will depend on the competitiveness of the quality of resins. General properties of LLDPE are at least equivalent, only and often superior to those of LDPE. Only optical properties are inferior to those of classical LDPE. This problem has now been solved by the development of highly transparent grades. (Edited author abstract) In French.

**081575 EQUIPMENT AND PROCESSING UPDATE FOR THE BLOWN-FILM EXTRUSION OF LINEAR LOW-DENSITY POLYETHYLENE.** LLDPE molecule has no long-chain branching and only a few short side chains, primarily the result of copolymerizing polyethylene with certain  $\alpha$ -olefins. These short side chains alter the processing characteristics chiefly by changing the molecular-weight distribution. This provides a film with superior mechanical properties, no entanglement, and good draw-down ability, but it reduces the ease of extrusion and bubble stability. There are arguments for both narrow and wide die gaps for processing LLDPE. Narrow gaps generally result in better machine-direction (MD) tear resistance, downgauging potential, and orientation balance in the film than wide gaps. However, the benefits are obtained by adding processing aids to the resin to prevent melt fracture. Wide die gaps offer reduced costs while providing higher extrusion rates, lower pressures, and better optics. Die-lip heating zones are sometimes added to provide additional heat to delay the onset of melt fracture. This eliminates the processing aids.

**081577 STRUCTURAL DISTRIBUTION OF LINEAR LOW-DENSITY POLYETHYLENES.** Molecular and crystalline structures of linear low-density polyethylenes (LLDPE) were investigated by a series of characterization techniques. Molecular structural characteristics were elucidated by temperature-rising elution fractionation (TREF) and solvent-gradient elution fractionation (SGEF). A bird's eye view and a contour map of LLDPE obtained by a combination of TREF and size exclusion chromatography exhibited a broad and multimodal chemical composition distribution (CCD), in contrast to a sharp and single CCD of conventional high-pressure low-density polyethylene (HP-LDPE). Short chain branching (SCB) was found to decrease with increase of molecular weight by SGEF technique. Thermal analysis of cross-fractions proved that a characteristic broad endothermic curve of LLDPE is attributable to its broad and

multimodal CCD. Then, using DSC results, an indicative index (DI) which expresses the degree of the distribution of lamellar crystal thickness is proposed. DI was found to be sensitive both to CCD and to a kind of SCB. (Edited author abstract). 31 Refs.

**081578 MORPHOLOGICAL EXPLANATION OF THE EXTRAORDINARY FRACTURE TOUGHNESS OF LINEAR LOW DENSITY POLYETHYLENES.** The fracture toughness of commercial linear low-density polyethylenes (LLDPE) has been found to be extraordinarily high relative to commercial low-density (LDPE) and high-density (HDPE) polyethylenes in previously reported investigations. The present investigation shows that this extraordinary fracture toughness cannot be explained by differences in molecular structure variables, such as molecular weight, long-chain and short-chain branching, fractional crystallinity, and comonomer content. Instead, the presence of a second soft phase, which was extractable with a weak solvent, in a hard semicrystalline matrix was discovered by morphological investigations. This second phase arises from the extreme compositional heterogeneity of the copolymers which comprise these LLDPE resins. No evidence for a similar morphological entity was found in LDPE and HDPE resins. This finding provides persuasive evidence that this very-low-crystallinity second phase performs a function similar to that of the rubberlike second phase in other high impact resins and, thus, leads to the observed extraordinary fracture toughness of LLDPE resins. Evidence for the nature and existence of this second phase is given from temperature-rising elution fractionation and scanning electron microscopy investigations. (Edited author abstract). 7 Refs.

**081579 LINEAR LOW DENSITY POLYETHYLENES AND THEIR BLENDS: PART 5. EXTENSIONAL FLOW OF LLDPE BLENDS.** The uniaxial extensional flow at 150°C of two series of blends: I. LLDPE/LLDPE and II. LLDPE/LDPE was examined in full range of concentrations as well as that of accessible in the rheometer strains and strain rates. It was concluded that Series-I blends containing different LLD-type polymers are miscible. Their properties can be predicted on the basis of molecular weight and molecular weight distribution. By contrast, excepting low concentration limits, blends of Series-II are immiscible. Both series show strain hardening, due to higher values of the maximum strain at break. Series-II seems to be superior (under the test conditions). The stress growth function in shear, computed from the frequency relaxation spectrum, provided a good prediction of the linear viscoelastic component of the stress growth function in uniaxial extension. **081582 DETERMINATION OF THE POLARITY OF CARRIER TRAPS IN  $\gamma$ -IRRADIATED POLYETHYLENE BY TEMPERATURE GRADIENT THERMALLY STIMULATED CURRENT.** Thermally stimulated current (TSC) and thermoluminescence (TL) measurements have been used widely to study trapped carriers in insulating films under high electric field or irradiation (X-ray or  $\gamma$ -ray). However, in insulating films, the polarity of carrier traps whether electron traps or hole traps, has not been clarified. Some investigations of the polarity of trapped carriers in  $\gamma$ -irradiated polymers by using a temperature gradient increasing with time have been reported, and the forementioned problem has been pointed out. Therefore, the authors have examined whether or not a space-charge field is formed in  $\gamma$ -irradiated polyethylene films. 8 refs.

**081583 RELATIONSHIP BETWEEN THE MECHANICAL RELAXATIONS IN THE  $\alpha$  ZONE AND THE CALORIMETRIC TRANSITIONS IN LOW DENSITY POLYETHYLENE.** The  $\alpha$ -relaxation spectra of LDPE, irradiated and unirradiated, has been compared with their calorimetric thermograms. There exists a correlation between the two mechanical relaxations that appear in the  $\alpha$  zone and the two fusion peaks observed in the calorimetric thermograms, confirming that the parameter that governs the temperature of the relaxations  $\alpha_1$  and  $\alpha_{II}$  is the most probable crystallite thickness, whereas the height of the  $\alpha$ -relaxation zone, as measured by means of  $\tan \delta_{max}$ , depends on the total crystalline content of the sample. (Author abstract) 16 refs.

**081584 SURFACE MODIFICATION. I. GRAFT POLYMERIZATION OF ACRYLAMIDE ONTO LOW-DENSITY POLYETHYLENE BY  $Ce^{4+}$ -INDUCED INITIATION.** Polyacrylamide was grafted onto a hydroxylated LDPE (low-density polyethylene) surface yielding a highly hydrophilic and stable new surface. LDPE was first oxidized by chromic acid and then reduced with diborane to form a hydroxyl-rich surface. Polymerization was then initiated by  $Ce^{4+}$ /HNO<sub>3</sub> solution. X-ray photoelectron spectroscopy and Fourier transform-IR/attenuated total reflection were used for elemental analysis and identification of the functional groups introduced. (Author abstract) 17 refs.

Batch, Christopher (Univ of Florida, Gainesville, FL, USA); Yahiaoui, Ali. *J Polym Sci Part A* v 25 n 12 Dec 1987 p 3479-3488.

**081585 LOW DENSITY POLYETHYLENE (LDPE/LLDPE).** Low density polyethylene (LDPE) continues to be the standard plastic with the highest tonnage figures alongside PVC. In 1986, worldwide installed production capacity for LDPE was some 14 m.t. Present-day LLDPE capacity in Western Europe can be expected to double by the start of the 1990s. After an

increase in the consumption of LDPE of some 20% per annum in the 1960s and up to the first oil crisis in 1973, the period from 1974 to 1979 still saw an average annual growth of 5 to 6%, up to more than 4 m.t. The range of different low-density polyethylenes available (LDPE, EVA and EA copolymers, LLDPE, VLDPE) means that processors and users have a broad basis of materials from which to fulfil the requirements of different applications. The combination of individual products, either by blending or by coextrusion, will serve to open up further fields of application for low density polyethylene.

**081587 BRANCHING IN LOW DENSITY POLYETHYLENE BY  $^{13}C$ -NMR.** An optimized experimental procedure has been developed for the  $^{13}C$ -NMR analysis of polyethylenes. These analyses were performed at 62.5 MHz in 60-80 (w/w)% mixtures in trichlorobenzene. Signal sensitivity is enhanced by operating at 100°C rather than higher temperatures. Solutions were prepared by holding the polymer-solvent mixtures at 155-160°C before cooling to the analysis temperature. This solution procedure, which is used also in size exclusion chromatography of polyethylenes, reduces NMR line widths and increases carbon spin-spin relaxation times. Branch concentrations measured are qualitatively similar but quantitatively different from those in earlier reports where shorter NMR delay times were employed. (Edited author abstract) 43 refs.

**081588 DEVELOPMENT OF CRYSTALLINE STRUCTURE DURING TUBULAR FILM BLOWING OF LOW-DENSITY POLYETHYLENE.** Development of crystalline structure during the tubular film blowing of low-density polyethylene was investigated, using wide-angle X-ray diffraction technique, low-angle light scattering, and scanning electron microscopy. In the study, commercial grades of both high-pressure low-density polyethylene (HP-LDPE) and low-pressure low-density polyethylene (LP-PDPE) (also, commonly referred to as linear low-density polyethylene, LLDPE) were used. The applied stresses at the freeze line were determined using theoretical expressions. These applied stresses were used to interpret the crystalline axes orientation in the tubular blown films. It was found that the magnitude of  $S_{11F}$  is an important process parameter to be a determining factor in the distribution of fibrillar nuclei and crystalline texture, as well as film anisotropy. (Edited author abstract) 30 refs.

**081589 STUDY OF POLYOLEFIN GEL IN ORGANIC SOLVENTS: II. STRUCTURE AND MORPHOLOGY OF BRANCHED LOW DENSITY POLYETHYLENE GEL IN ORGANIC SOLVENTS.** Two kinds of branched low density polyethylene (LDPE) gels were prepared by cooling a solution rapidly (a rapid cooling gel) and slowly (a slow cooling gel), and the morphology as well as the structure of the gels were studied. Moreover, gel-melting temperature  $T_m^g$  was measured and its dependence on polymer concentration, molecular weight, and branching degree was also investigated. A range of weight-average molecular weight of samples used is from  $8.7 \times 10^4$  to  $17.5 \times 10^4$ . For both rapid and slow cooling gels,  $T_m^g$  increases with increasing polymer concentration as well as molecular weight, but decreases with increasing branching degree. The minimum polymer concentration  $C^*$  for gel formation and the form of crystallites in gels depend on the cooling rate of a solution considerably, though the difference in  $T_m^g$  between the rapid cooling gel and the slow cooling one for a same sample is little. (Edited author abstract) 37 refs.

**081590 INFLUENCE DES METHODES DE MISE EN OEUVRE DU POLYETHYLENE (PEBD) SUR SON COMPORTEMENT SOUS HAUTE TENSION CONTINUE.** [Influence of the LDPE Manufacturing Process on Its Behavior under Electric Stress]. In order to improve the insulating properties of low density polyethylene (LDPE) under electric stress, a systematic study of LDPE based materials has been conducted. This investigation has been made by measuring, using the pressure wave propagation method, the evolution of charge or dipole distributions in samples submitted to a high voltage gradient. Two pure LDPE resins of different origins were used to prepare planar geometry samples, identical in any other respects. The behavior of these samples is compared, for various applied fields, temperatures and chemical formulations of the electrodes. From these results, new information relative to charge storage and transport in these materials is obtained. It is shown that, by studying directly the influence of the chemical composition of materials on their electrical properties, it will be possible to define high performance insulations. (Author abstract) In French. 8 refs.

**081593 NUCLEATION OF LOW DENSITY POLYETHYLENE BY HIGH DENSITY POLYETHYLENE.** A nucleating agent produced from the same monomeric unit as the polymer to be nucleated has similar chemical and physical properties and can be used to direct the morphology of LDPE regardless of the size of the spherulites. It is also possible to generate a modified shish-kebab structure with a macroscopic core of high density polyethylene surrounded by a LDPE matrix or a transcrystalline morphology in LDPE due to the high nucleation density of the HDPE surfaces in contact with LDPE. This letter deals with the principle of the PE-PE nucleation and some basic results. 11 Refs.

## Manufacture

**081594 SUROVINOVA ZAKLADNA PRO VYROBU ETHENU.** [Raw Material Base for the Production of Ethylene]. The progress of the raw material base for the production of ethylene is analyzed on the basis of available literature data. Although pyrolysis represents a process exceptionally demanding with regard to both energy and raw materials, in the foreseeable future it will remain the basic process in petrochemical industry, essentially in the same form as today. Progress will be directed to its innovation aimed at achievement of higher energy efficiency, higher yield, and an expedient utilization and combination of the processed raw materials, or resources of light hydrocarbons isolated from natural gas, and the development of new resources by utilization of heavy petroleum fractions. (Edited author abstract) In Czech. 27 refs.

**081596 RELATIONSHIP BETWEEN TENSILE STRENGTH AND MOLECULAR WEIGHT OF HIGHLY DRAWN POLYETHYLENES.** Recently, we reported a series of tensile tests on a wide range of highly drawn polyethylenes made from commercially available polymers of differing polydispersity. It is of great importance to be able to calculate the strength of a polymer from a knowledge of the molecular weight distribution, but it is then necessary to postulate a model for the strengthening effect of the different weight components. The excellent correlation between the calculated and experimental values shows that the simple weight-average Flory model is adequate to determine the strength of polydispersed polyethylenes. 6 refs.

**081597 STRUCTURAL ORGANIZATION AND MECHANICAL PROPERTIES OF HIGH DENSITY POLYETHYLENE FILLED WITH SHORT GLASS FIBRES.** The influence of the structural organization of a short-fiber filler (effect of agglomeration, average length,

orientation) on the strengthening of high density polyethylene has been analyzed. Mechanical properties of the material under impact loads and in tensile tests at a constant rate of stretching have been investigated. The degree of agglomeration of fibers was found to grow with increase in their relative length, and with increasing degrees of filling. (Author abstract) 8 refs.

**081598 DYNAMIC MECHANICAL PROPERTIES OF POLYETHYLENE AND POLYBUTYLMETHACRYLATE COMPOSITES OBTAINED BY STRETCHING POLYETHYLENE IN A LIQUID MONOMER FOLLOWED BY ITS POLYMERIZATION.** From analysis of the temperature dependence of dynamic mechanical properties, the authors make a comparative study of the phase structures of mixtures of PE with polybutylmethacrylate formed by mechanical mixing in an extruder or as interpenetrating polymer networks. The continuity of both phases for a high degree of dispersion in the interpenetrating networks determines the higher indices of the physicomechanical properties as compared with mechanical mixtures with a grossly dispersed structure. (Edited author abstract) 10 refs.

**081599 NEW MODEL FOR THE HIGH MODULUS AND STRENGTH PERFORMANCE OF ULTRADRAWN POLYETHYLENES.** A new morphological model is discussed which is based on the relation of tensile modulus and strength to the macrofibrillar dimensions (aspect ratio) and the shear modulus of ultrahigh molecular weight polyethylene fibrillar structures of draw ratio  $DR \leq 200-300$ . Such structures were obtained by solid state deformation of the as-received powder and solution grown crystals using an extrusion-drawing process. According to this model, the highest tensile modulus and tensile strength values that can be obtained are 212 GPa and 13.3 GPa, i.e., significantly close to the theoretically calculated values. (Author abstract) 23 refs.

**081600 NEW ASPECTS OF YIELDING IN SEMICRYSTALLINE POLYMERS RELATED TO MICROSTRUCTURE: BRANCHED POLYETHYLENE.** The application of thermodynamics of eutectoid copolymers and a generalized Tabor relation to relationships between mechanical properties (microhardness, yield stress) and microstructure in semicrystalline polymers is considered. The approach is illustrated by results on melt-crystallized low density polyethylene, investigated near the yield point at different temperatures. The success of the approach emphasizes that semicrystalline polymers, despite being viscoelastic heterogeneous systems, give rise to a yielding process entailing the irreversible deformation of a larger number of crystals within cooperative super-structure units. Microhardness provides, within this context, a unique measure of the crystal size average. Comparison of calculated and experimental data favors the view of deformed crystals containing basal defective surface boundaries ('meso-crystals') which yield cooperatively. (Author abstract) 22 refs.

**081601 RELATIONSHIP BETWEEN MECHANICAL PROPERTIES AND FIBER STRUCTURE FOR ZONE-DRAWN POLYETHYLENE FIBERS.** Mechanical properties of highly drawn polyethylene fibers produced by a continuous zone-drawing method were studied and related to fiber structure. Young's modulus and tenacity increased linearly with an increase in the

drawing stress and also showed a good linear relationship with the amorphous birefringence. The stress-optical coefficient in amorphous phase depended strongly on the drawing temperature; its value was  $0.5 \text{ GPa}^{-1}$  for the fibers drawn at the temperature above  $115^\circ\text{C}$ . Linkages of the crystalline blocks formed at degrees of crystallinity beyond 77%, and this resulted in the high Young's modulus. Tenacity was dependent mainly on the degree of crystallinity. (Edited author abstract) 21 refs. In Japanese.

**081602 POLIETILENSKE MJESAVINE - MEHANICKA SVOJSTVA I STRUKTURA.** [Polyethylene Mixtures - Mechanical Properties and Structure]. This paper discusses the compatibilities of polymer blends prepared by the melt blending process: low density with high density polyethylene (LDPE/HDPE blends) and low density with medium density polyethylene (LDPE/MDPE blends). The mechanical and dynamic mechanical properties and crystal structure of polyethylene blends have been examined over the whole range of concentrations. The results of mechanical testing have been elaborated and systematized statistically and presented graphically. The results are discussed according to the rule of additivity, while the structural models are discussed in terms of the compatibility of the two systems. The systems behave differently in different concentration ranges: up to 50 percent weight of LDPE the systems are compatible or partially compatible, and over 50 percent weight of LDPE they are incompatible. (Edited author abstract) 26 Refs. In Serbo-Croatian.

**081603 AGEING EFFECTS AND INTERNAL STRESSES IN QUENCHED UNFILLED AND CLAY-FILLED HIGH DENSITY POLYETHYLENE.** The stress relaxation and creep behaviour of high density polyethylene (HDPE), unfilled or filled with clay particles, were measured after different ageing times after quenching from  $120^\circ\text{C}$ . The measurements were performed at room temperature in the uniaxial extension mode. Ageing time had a pronounced influence on the viscoelastic properties, e.g. the creep curves shifted to longer times with increasing ageing time. The internal stresses, as evaluated from stress relaxation data, were found to increase markedly when the ageing period was extended, and it was suggested that this behaviour may be associated with relaxation of thermal residual stresses. It was furthermore suggested that the change in residual stresses, in addition to the physical ageing process, could also affect the ageing behaviour of HDPE, i.e. the change in viscoelastic properties with ageing time. Clay addition changes the ageing behaviour of HDPE, which could be attributed to a change in the internal stress dependence of the ageing time and/or to a difference in the physical ageing process. **081604 DELAYED ELASTIC RECOVERY OF HARDNESS INDENTATIONS IN POLYETHYLENE.** The depth of Vickers microindentations in high density, low density and linear low density polyethylenes has been studied by two-wave interferometry. The evolution of the delayed depth recovery is explained in terms of the Burgers model of viscoelastic behavior. The numerical parameters associated with the model are related to the crystallinity, elastic modulus and yield stress of the polyethylenes studied. (Author abstract) 16 Refs.

## Medium Density

**081605 EFFECT OF RESIDUAL STRESS ON CRACK PROPAGATION IN MDPE PIPES.** Crack propagation behavior in single edge notched specimens prepared from medium-density polyethylene (MDPE) pipe is examined under creep condition. The crack grown from an exterior notch (inbound) initiated faster than that grown from an interior notch (outbound). Subsequently, the outbound crack propagated monotonically to ultimate failure. The inbound crack showed anomalous behavior involving two arrest stages prior to ultimate failure. The pipe is found to possess substantial residual stresses. The energy release rate for each case was calculated taking into account the respective residual stress distribution. The fact that the rates of crack propagation are not a unique function of the energy release rate indicates that the fracture is also influenced by morphological gradients imposed by processing conditions. (Author abstract) 24 refs.

## Melting

**081606 EFFECT OF ORIENTATION ON MELTING OF POLYETHYLENE.** Uniaxial orientation induced by cold drawing has a marked effect on the properties of crystalline polymers. Not least among these changes are the observed melting points with draw ratio, and the alterations to the crystalline morphology. In the present paper, the effect of uniaxial orientation on the melting point (m.p.) of polymers is discussed in general and applied to polyethylene. The increase in m.p. with orientation is attributed to the increase in configurational entropy of the extended melt into which the crystallite melts. An equation is derived relating the observed m.p. to draw ratio. (Edited author abstract) 10 refs.

**081607 THERMODYNAMIC CHARACTERISTICS OF LAMELLAS AND THEIR SURFACES IN BULK POLYETHYLENE FROM DIFFERENTIAL SCANNING CALORIMETRY DATA.** The melting of specimens of isotropic linear polyethylenes of different MM, crystallized under different conditions, and also of specimens in which the non-ordered component has been removed by etching is studied by differential scanning calorimetry, and the thermodynamic characteristics are compared with the geometrical parameters of the lamellas. The non-ordered component of polyethylene has hardly any effect on its true melting point. The inter-chain cooperative melting parameter corresponding to the thickness of the crystalline core of a lamella is evaluated. It is confirmed that double folds can be formed. (Edited author abstract) 19 refs.

**081608 CRYSTALLIZATION AND MELTING OF POLYETHYLENE OXIDE IN SYSTEM WITH A JOINTLY CURED DENSELY CROSSLINKED POLYMER.** The calorimetric method has been employed to study the patterns of crystallization and melting of polyethylene oxide in a system with a melamine formaldehyde polymer cured jointly with it. The topology of the spatial densely crosslinked polymer network and chemical binding of the terminal groups of polyethylene oxides were found to have a strong influence on its behavior on crystallization and melting. The sharp difference in the chemical structure of PEO and MF(Melamine Formaldehyde)-polymers ensures phase separation in the MF-PEO systems even for a length of the linear component corresponding to the dimer. The formation of the phase composition in such systems occurs in conditions of the chemical curing reaction at the end of which the disperse phase of the linear component is trapped in the rigid MF

matrix, which determines some aspects of its behavior. 8 refs.

## Microscopic Examination

**081609 FURTHER ELECTRON MICROSCOPE OBSERVATIONS ON POLYETHYLENE. I. GRANULE STRUCTURE OF THE MELT AS AN ARTIFACT.** There are still two opinions on the fine structure of polymer melts and glasses: (a) that the structure is similarly homogeneous to that in lower molecular weight materials and (b) that the structure shows larger short-range order regions (2-20 nm), which consist of bundled segments of the chain molecules. Whereas opinion a relies more on indirect methods of investigation, opinion b is based mainly on fine granular structures which become visible in electron microscope investigations of surfaces of glassy solidified polymers. Such a fine structure can now be observed directly in a polyethylene melt. However, the structure is exposed as an artifact, so opinion a is supported. (Edited author abstract) 35 refs.

## Microstructure

**081610 EFFECTS OF CONDITIONS OF CHLORINATION ON THE MICROSTRUCTURE OF CHLORINATED POLYETHYLENE.** The microstructure of specimens of polyethylene (PE) chlorinated in solution and suspension are subjected to a comparative study by PMR and IR spectroscopy. The content of methylene groups occupying different positions in the chlorinated polyethylene chain was compared with the theoretically expected values from the course of chlorination in solution and in suspension with respect to the type of 'hindered' substitution reaction. Double substitution at any repeating unit is completely excluded in the case of chlorination in solution. (Author abstract) 14 refs.

## Molecular Structure

**081612 STRUCTURE AND MOLECULAR MOBILITY OF POLYMER CARRIERS AND METALLOCOMPLEXES BASED ON THEM AS REVEALED BY NMR RELAXATION.** Using NMR pulse methods the authors have studied from the drops in free induction and the relaxation times the structure and molecular mobility of HDPE, polymer carriers based on polyacrylic acid grafted to PE and the metallocomplexes Cu(II), Ni(II) and V(IV) fixed on them in the temperature interval 333-403 K. It was established that the initial PE contains a crystalline and two amorphous phases -

intermediate and surface. Grafting the acid and formation of the metallocomplexes did not change the polymer structure. It is shown that the metallocomplexes form in those loose surface layer of the polymer carrier. (Author abstract). 12 Refs.

**081613 PROPERTIES OF ORIENTED FIBERS OF HIGH-MOLECULAR-WEIGHT POLYETHYLENES.** Fibers with a set of unique properties can be obtained by formation from 2-5% solutions of PE with mol. wt. =  $(1-2) \cdot 10^6$  and subsequent orientational drawing: high tensile strength, including 'unit' strength, a high modulus of elasticity, low compliance, and small changes in length on heating to temperatures  $\leq 140^\circ\text{C}$ . These properties are due to the high orientation of the macromolecules which can be attained in optimum conditions of formation of the initial structure and drawing. 11 refs.

## Molten

**081614 TIME-RESOLVED EXPERIMENTS ON THE EXCITON TRANSFER PHENOMENON IN MOLTEN POLYETHYLENE.** The paper presents a time-resolved study of rapid exciton migration in polyethylene (PE) by means of pulse radiolysis and laser photolysis experiments. Despite the high viscosity of molten PE blended with substances such as a phenol, diphenylamine or benzophenone the most important part of the radiation-generated scavenger radicals is formed in times  $< 40$  ns. By comparison with laser photolysis experiments with molten PE and liquid-state pulse radiolysis in alkanes the rapid radical formation is explained in terms of the intramolecular exciton migration with subsequent dissociative transfer to the additive. (Author abstract). 14 Refs.

**Morphology** See Also COPOLYMERS—Structure; POLYPROPYLENE—Morphology.

**081615 SPHERULITIC MORPHOLOGY IN POLYETHYLENE AND ISOTACTIC POLYSTYRENE: INFLUENCE OF DIFFUSION OF SEGREGATED SPECIES.** Morphological consequences of a localized diffusion of segregated species at crystal growth fronts have been studied in two specific contexts: (1) variation of texture in spherulites grown in unfractionated polyethylene over a range of crystallization temperatures mostly in regime II, and (2) development of elongated lamellar habits in spherulites of a polymer (isotactic polystyrene) whose native crystal habit is regularly polygonal. In relation to (1) it is shown that, as crystallization temperature is varied, there is a correlation between mean thickness of stacks of lamellae and an averaged diffusion range of segregated molecules of lower molecular weight. It is noted that the lamellar organization appears to be significantly different in polyethylene fractions. In relation to (2) it is shown that principal contributors to the evolution of spherulitic texture from hedritic precursors are fragmentation of lamellae by screw dislocations and radially biased growth under the influence of concentration gradients of segregated species. (Author abstract) 31 refs.

**081616 MORPHOLOGY AND MECHANICAL**

**PROPERTIES OF POLY(ETHYLENE TEREPHTHALATE)-POLY(HYDROXYBENZOIC ACID) AND POLYCARBONATE BLENDS.** Blends of an engineering plastic; polycarbonate (PC) and a liquid crystalline polymer; random copolymers of the poly(ethylene terephthalate) and the poly(hydroxybenzoic acid) were prepared in an internal mixer. Fibers were extruded from the capillary rheometer and spin-drawn at varying draw ratios. The morphology and the mechanical properties were investigated by DSC, SEM, polarizing optical microscopy, X-ray diffraction, and tensile tests. SEM studies revealed that the liquid crystalline polymer (LCP) formed finely dispersed spherical domains with a diameter of 0.2-2.0 micron in the PC matrix and the inclusions were deformed from the spherical droplets to fibrils as the draw ratio increased. (Edited author abstract) 18 refs.

**081617 MOLECULAR SEGREGATION AND NUCLEATION OF POLY(ethylene OXIDE) CRYSTALLIZED FROM THE MELT. III. MORPHOLOGICAL STUDY.** Solvent extraction followed by DSC, optical microscopy, and transmission electron microscopy show morphological evidence of molecular segregation for binary mixtures of poly(ethylene oxides) (PEO). Two segregation types, namely microscopic and macroscopic segregation, have been found. A special etching method for PEO has been developed, and the crystalline textures of bulk samples crystallized at different temperatures for different molecular-mass mixtures are reported. A linkage between optical and electron microscopy is suggested. The morphology of PEO binary mixtures is crystallization-temperature and molecular-mass dependent. (Author abstract). 20 Refs.

## Optical Properties

**081618 COMPARISON OF THE OPTICAL PROPERTIES OF ELECTRON-IRRADIATED AND THERMALLY-TREATED POLYETHYLENE.** The authors examine the optical properties of electron-irradiated and thermally-treated LDPE, UV and IR spectroscopy and luminescence have shown that on electron irradiation and thermal treatment of PE the processes of formation of the oxygen-containing groupings and conjugated bonds take a different course. Thermal treatment of PE leads to more profound changes in the polymer structure. (Edited author abstract). 12 Refs.

Bogdan, L.S. (Shevchenko State Univ, Kiev, USSR); Lisovenko, V.A.; Pas'ko, S.P.; Sandul, G.A. *Polym Sci USSR* v 29 n 4 1987 p 785-790.

**Oxidation** See Also COATINGS—Adhesion; TEXTILES—Aging.

**081619 DIELECTRIC STUDY OF OXIDATION IN THE AMORPHOUS AND CRYSTALLINE REGIONS OF LOW DENSITY POLYETHYLENE WITH ANTIOXIDANT.** The effect of antioxidant on oxidation both in the amorphous and crystalline regions of low density polyethylene (PE) was investigated. Degradation was carried out by oxidation using thermal aging below the melting point of PE subsequent to  $\gamma$ -irradiation. Dielectric measurement was carried out to compare the oxidation in the amorphous region and that in the crystalline. It was found that the antioxidants had little effect on oxidation in the crystalline region, though the oxidation in the amorphous region was suppressed by antioxidant. This is interpreted in terms of dispersion of the antioxidant in PE, which is suggested by DTA study. (Edited author abstract) 11 refs.

**081620 NEW APPROACH TO THE MEASUREMENT OF POLYMER PHOTOOXIDATION.** In an attempt to eradicate many of the problems associated with outdoor and accelerated testing of polymeric formulations, an apparatus was constructed for the sensitive measurement of oxygen uptake into a polymer during its incipient stages of photooxidation. The photooxidation curves of certain HDPE and LDPE formulations demonstrate a first order asymptotic approach to a limiting value which corresponds to the initial number of reactive centers that are available in the material for oxygen attack. An equation for oxygen uptake as a function of time is derived which incorporates the asymptotic value together with a constant whose value reflects the rate at which the asymptote is approached. (Edited author abstract) 40 refs.

Bigger, S.W. (Univ of Melbourne, Parkville, Aust); Delatycki, O. *J Polym Sci Part A* v 25 n 12 Dec 1987 p 3311-3323.

**081621 OXIDATION OF SOLID POLYETHYLENE FILMS: EFFECTS OF BACKBONE BRANCHING.** The oxidation rates and product distribution of a series of linear and branched polyethylene films have been studied when initiated by  $\gamma$ -irradiation. Branch groups in laboratory-synthesized samples ranged from ethyl to  $\text{C}_{16}$ -H<sub>33</sub> - and were at levels comparable with those found in commercial linear-low and low-density polyethylenes. In the complete absence of stabilizers and at the controlled rates of radical formation possible with  $\gamma$ -irradiation, all of the polyethylene samples oxidized at essentially the same rate to give the same mixture and distribution of products. (Edited author abstract) 29 refs.

**081623 STUDY OF THE CHANGE OF CRYSTALLINITY OF POLYETHYLENE ON OXIDATION BY INVERSE PHASE GAS CHROMATOGRAPHY.** Inverse-phase gas chromatography has been used for monitoring the oxidative degradation of low density polyethylene, which has great industrial importance. Polyethylene was oxidized in a gas chromatographic column at  $145^\circ\text{C}$  with an oxygen flow of 10 mL/min for different periods. After oxidation for a specified period, the crystallinity and solvent interaction parameters were monitored. For crystallinity studies, the solvent probe was n-decane, and for solvent interaction these were n-decane, o-xylene, n-butanol, and n-butyl acetate. With oxidation, there was a gradual fall in crystallinity, and after 15 h the crystallinity was practically nil. Total loss of crystallinity also occurred at  $175^\circ\text{C}$  with 1 h passage of oxygen. This has also been confirmed by differential scanning calorimetry. The specific retention volumes of polar solvents showed a sharp increase with oxidation. The results, which are different from that reported in the literature, have been explained. (Author abstract) 13 refs.

**081624 SURFACE AND BULK OXIDATION OF LOW-DENSITY POLYETHYLENE UNDER UV-IRRADIATION.** The bulk and surface effects of UV-irradiation are compared in relation to oxidative degradation in blow-extruded films of low-density polyethylene. These studies were carried out using transmission and reflectance infrared spectrophotometry films of different thickness and ATR prisms of different incident angles were used. The results indicate that at the very beginning of the reaction the concentration of oxidation products is higher in the bulk of the films than on the upper surface layer penetrated by the infrared beam. With increase of irradiation time the situation is reversed, with an increase of oxidation product concentration on the surface. These results are in contrast to the generally accepted idea that photo-oxidation phenomena are restricted to a thin surface layer of polymers. (Author abstract). 11 Refs.

**081626 OXIDATION BEHAVIOR OF HIGH STRENGTH CHAIN-EXTENDED POLYETHYLENE FIBERS.** The resistance of oxidation of polyethylene fiber intended for engineering applications has been compared with that of conventional polyethylene films. The highly ordered fiber was appreciably more resistant to  $\gamma$ -initiated oxidation and somewhat more resistant to photo-oxidation. Oxidation products from the  $\gamma$ -initiated oxidation were highly ordered with respect to the fiber axis as shown by polarized infrared spectroscopy. Photo-oxidation products showed random orientation, possibly as a result of the more extensive chain scission and that must accompany the photo-process. Despite the higher resistance of  $\gamma$ -radiation damage of the chain-extended fiber structure as compared to unoriented film, the irradiated fiber did show a slow post-irradiation oxidation. **081627 RECONSTRUCTION OF THE INTERFACE OF OXIDATIVELY FUNCTIONALIZED POLYETHYLENE AND DERIVATIVES ON HEATING.** Oxidation of low-density polyethylene film with aqueous chromic acid results in a material having hydrophilic carboxylic acid and ketone groups in a thin oxidatively functionalized interface. This interface is indefinitely stable at room temperature. On heating under vacuum, it rapidly becomes hydrophobic and similar in its wettability to unfunctionalized polyethylene film. The progression of the contact angle with water from the initial value to the final value follows kinetics that suggest that the polar functional groups disappear from the interface by diffusion. The magnitude of the apparent diffusion constant derived from these studies can be described approximately by an Arrhenius equation over a significant portion of the temperature range explored, with an Arrhenius activation energy of diffusion of  $\approx 50$  kcal/mol. Comparison of the properties of interfaces composed of carboxylic acid groups with those containing other species demonstrates that the structure of the interfacial groups also significantly influences the rate of reconstruction.

## Phase Transitions

**081628 GLASS TRANSITION AND MELTING BEHAVIOR OF POLY(ETHYLENE-2,6-NAPHTHALENEDICARBOXYLATE).** On the basis of thermal analysis the heat capacities of both solid (230-350 K) and liquid (390-600 K) poly(ethylene-2,6-naphthalenedicarboxylate) (PEN) have been established by measurements on over 30 samples. The heat capacity of the solid is structure-independent to 300 K. Between 300 and 390 K, a pre-glass transition increase in heat capacity is observed for the amorphous samples of the polymer. Above the glass transition temperature (390 K), poorly crystallized PEN shows a rigid-amorphous fraction (up to 0.2). The rigid-amorphous fraction starts to gain mobility at about 430 K and reaches zero after melting of the low melting fraction of the polymer. The glass transition temperature on cooling changes logarithmically. The hysteresis of amorphous samples has been analyzed. The crystallization range was studied from 450 to 530 K by crystallizing on cooling from the melt and heating from the glass. (Edited author abstract) 26 refs.

## Photochemical Reactions

**081629 EFFECTS OF ELONGATION ON THE PHOTOCHEMISTRY OF POLY[ETHYLENE-co(CARBON MONOXIDE)].** Films of poly[ethylene-co(carbon monoxide)], P(E/CO), were cold drawn to various extensions. IR dichroism measurements showed that the molecular chains in the amorphous region were oriented along the direction of drawing. After UV irradiation the percent crystallinity and average crystallite size, as determined by X-ray diffractometry, increased for both undrawn and drawn samples. Also, the orthorhombic form in drawn samples increased at the expense of the monoclinic form during UV exposure. The formation of vinyl end groups increased with exposure and with extent of elongation as determined by IR spectroscopy, while the formation of acetyl end groups was strongly suppressed by orientation as determined by NMR spectroscopy. (Edited author abstract) 27 refs.

## Physical Properties See Also GAS PIPELINES—Plastics Applications.

**081630 PHYSICAL PROPERTIES OF THE SYSTEM POLY(ETHYLENE OXIDE)-RESORCINOL.** Physical properties of the system poly(ethylene oxide)-resorcinol have been investigated by X-ray diffraction, small-angle light scattering, polarization microscopy with crossed Nicols, and differential scanning calorimetry. Formation of a molecular complex is accompanied by changes in the crystalline and supermolecular spherulitic structure. Temperatures and heats of phase transformations have been determined. (Author abstract) 13 refs.

**081631 LOW-DENSITY POLYETHYLENE DEPTH PROFILE ANALYSIS BY PHOTOACOUSTIC SPECTROSCOPY.** Near-infrared photoacoustic spectra of polyethylene (1 mm slab) were taken in the modulation range 10-240 Hz, which corresponds to thermal diffusion layers in the 56-11  $\mu$ m range. Thick-layer spectra are very similar to polyethylene film transmission

spectra, but large differences are observed between the spectra taken at various modulation frequencies. The analysis of spectral intensity as a function of modulation frequency shows that peak intensity ratios of  $-\text{CH}_3$ ,  $=\text{CH}_2$ , and  $-\text{OH}$  groups, relative to that of methylene groups, increase as thinner, closer-to-surface polymer layers are sampled. From this we conclude that near-to-surface layers of solid polyethylene are richer in  $-\text{CH}_3$ ,  $=\text{CH}_2$  and  $-\text{OH}$  groups than the polymer bulk. (Edited author abstract) 42 refs.

**081632 AMORPHOUS ORIENTATION IN ZONE-DRAWN POLYETHYLENE FIBERS.** The amorphous orientation in highly drawn polyethylene fibers produced by a continuous zone-drawing method was studied by birefringence, X-ray and infrared measurements. Birefringence of the highly-drawn fibers exceeded the intrinsic birefringence of the crystals. Birefringence of the amorphous phase increased with the draw ratio, the ultimate value was 0.10. But birefringence of the crystalline phase remained at the constant value of the almost perfect orientation, 0.057. The reciprocal of amorphous birefringence was directly proportional to the value of the draw ratio squared. The extrapolated value according to the above relationship was found to be 0.21 for the intrinsic amorphous birefringence. A model of deformation mechanism in the zone-drawing process was proposed on the basis of shear or sliding deformation between the chain folded ribbons (interribbon unfolding) and within the chain folded ribbons (intraribbon unfolding). **081633 MEMORY OF SUPERSTRUCTURE OF DRAWN ULTRA-HIGH MOLECULAR WEIGHT POLYETHYLENE.** Ultra-high molecular weight polyethylene (UHMWPE) was drawn at 120°C and cooled to room temperature. The samples were annealed at various temperatures above the melting point at constant length. The superstructure which appeared when samples were cooled from the melt state was studied by small- and wide-angle X-ray analyses. The sample which had the highest molecular weight showed the strongest memory of structure even when it was kept in the melted state for a long time. But the samples with lower molecular weights did not show the memory so much. In general, the higher the temperature, the longer the treating time, and the lower the molecular weight of sample, the less the memory of structure was. The memory thus depended on the molecular weight of the samples. This memory could be attributed to the degree of entanglements in the amorphous molecular chains and to the tie molecules between fibrils formed in the sample before annealing. (Edited author abstract) 6 refs. In Japanese.

## Polymerization See POLYOLEFINS—Crosslinking.

## Processing

**081634 PROCESSING OF ULTRAHIGH MOLECULAR WEIGHT POLYETHYLENE.** The extent of recrystallization of nascent UHMWPE power is easily measured by calorimetry. Melting and recrystallization of nascent UHMWPE at 140°C can be suppressed by compression molding. Crystals of UHMWPE prepared from dilute solution show a peak melting temperature of 140°C and exhibit crystallinity up to 75.5% depending on crystallization temperature. Large changes in crystallinity result from drawing single crystal mats or compression-molded films. (Author abstract) 14 refs.

**081635 DRAWING-INDUCED CHANGES IN THE PROPERTIES OF POLYETHYLENE FIBERS PREPARED BY GELATION/CRYSTALLIZATION.** Fibers of ultrahigh molecular weight polyethylene were prepared by drawing dry specimens obtained by gelation/crystallization from solution. The maximum draw ratio ( $\lambda$ ) attained was 250. The properties of the fibers were assessed by measurements of density, birefringence, differential scanning calorimetry, infrared dichroism, sonic velocity, and dynamic modulus. The results have been analyzed in terms of a two-phase model of crystalline and amorphous regions. All properties approach a limiting value at a draw ratio of about 100. The degree of crystallinity and melting point decrease initially (for  $\lambda < 12$ ) and then increase rapidly with  $\lambda$  up to their limiting values. (Edited author abstract) 35 refs.

**081636 SCREW DESIGN IMPROVEMENTS FOR UNFILLED CROSS LINK POLYETHYLENE.** Over the last 10 years or more there has been no improvement seen in screw performance for the processing of crosslinkable polyethylenes like Union Carbide's HFDE 4201 and the newer-4202 material. This paper will give the results of the studies done with these popular materials. It will include performances as compared to the typical conventional mixing screws with respect to output rate, extrusion stability, melt temperature level, power usage and melt quality.

**081637 VISCOELASTIC BEHAVIOUR OF STABILIZED POLYETHYLENES IRRADIATED WITH GAMMA RAYS.** Two-cycle creep recovery penetration measurements at 150°C are used to determine the viscoelastic parameters for irradiated low density and linear low density polyethylenes, pure and with 0.5% antioxidant. The amplitudes and the time factors of each cycle are calculated using the mechanical model expression. From the differences between the creep parameters of the first and the second cycle, the contribution of the nonelastic component is considered. The efficiency of radiation crosslinking of different systems is discussed on the base of the corresponding compliances. (Author abstract) 6 refs.

**081638 CHARGE TRANSPORT IN IRRADIATED LOW-DENSITY POLYETHYLENE.** A study has been made of the remanent effects of nuclear radiation on charge transport in additive-free low-density polyethylene (LDPE) at 323 K. It was found that irradiation increased the conductivity of LDPE, with pure gamma radiation having a greater effect for a given absorbed dose than the mixed radiation of a thermal nuclear reactor. This increase in conductivity may be ascribed to an increase in trap density based on a trap-hopping conduction model. The measured current density also appears to be a function of  $F/n+1$ , where F is the applied field and n a positive number. (Author abstract) 16 refs.

**081639 MAGNETIC RESONANCE STUDIES ON CROSS-LINKS IN POLYETHYLENE AND ITS MODEL COMPOUND.** Difference in mobility was detected between the  $\gamma$ -irradiated and neutron-irradiated

eicosane by analysis of ESR spectra obtained by the spin-trapping method. Three kinds of cross-linked dimers were found by FI mass spectroscopy: saturated cross-linked dimers, cross-linked dimers having either one double bond or two. The relative intensities of these dimers were also different between the  $\gamma$  and neutron irradiated ones.  $^{13}\text{C}$ -NMR spectra were observed from the cross-linked n-eicosane.  $\text{CH}_2$  peaks in the NMR spectrum were clearly distinguished from others by the INEPT method. The analysis of the NMR spectra indicated that the majority of the cross-links formed were the H-type.  $^{13}\text{C}$ -NMR of irradiated PE obtained by the CP-MAS method was also discussed. (Edited author abstract) 5 refs.

**081640 EFFECT OF DOSE ON CREEP AND RECOVERY OF POLYETHYLENE.** The effect of high energy radiation on polyethylene is to crosslink it, and connect it into an elastic network above the melting point. In this paper the creep and recovery properties of a stabilized polyethylene subjected to doses from 100 to 870 kGy are measured at 150°C. Two cycles are measured - Creep I + Recovery I, and Creep II + Recovery II - mainly over period of 20 min. The creep or recovery behavior falls into three steps - immediate, fast and slow, and data are given for these steps together with the time parameter. The first cycle includes a non-recoverable creep which is almost absent in the second cycle. (Author abstract) 6 refs.

**081641 INFLUENCE OF THE NATURE OF LIQUID MEDIA ON THE MECHANICAL PROPERTIES OF IRRADIATED FILLED POLYETHYLENE.** In connection with the increase in heterogeneity of the modified polyethylene, evaluation of the stability of the acquired properties under conditions approaching service, under the combined action of liquid media and mechanical loads, was investigated. Type 15803-020 high-pressure polyethylene was used for the investigation. The fillers were highly dispersed silicon dioxide  $\text{SiO}_2$  (type A-175 aerosol) and titanium dioxide ( $\text{TiO}_2$ ) of the rutile form. The strength and deformation properties in tension of the modified polyethylene were investigated on a tensile machine in water, normal alcohols, dioxane and carbon tetrachloride. Modification of polyethylene by filling and ionizing radiation provides a positive result under conditions of the action of adsorption-active liquid media characterized by low solubility in the polymer (alcohols, dioxane). 5 refs.

**081642 FEATURES OF STRUCTURAL CONVERSIONS IN ORIENTED POLYETHYLENE AS A RESULT OF EXPOSURE TO IONIZING RADIATION.** The features of structural conversions in oriented samples of high density polyethylenes following irradiation at 20 and 100°C have been investigated. The character of the change in the structural parameters suggest that in oriented polyethylene radiation degradation makes a considerably greater contribution than in the non-oriented polymer. A possible reason for the effect observed is the presence of a large number of stressed communicating molecules in the amorphous phase. (Author abstract) 19 refs.

**081643  $\gamma$ -IRRADIATION OF POLYETHYLENE STUDIED BY POSITRON ANNIHILATION.** Investigations were performed on polyethylene of about 170 mg  $\text{cm}^{-2}$  thickness. The equipment used for  $\gamma$ -irradiation in

air was either a  $^{60}\text{Co}$  source or irradiated fuel elements with dose rates of 0.1 and 12.5 kGy  $\text{h}^{-1}$ , respectively, up to doses of 1000 kGy. For positron lifetime measurements a conventional fast-slow coincidence circuit was used with a time resolution of 350 ps (FWHM) for  $^{22}\text{Na}$  energy windows. It was possible to describe the distinguishable influence of dose and dose rate by logarithmic functions. 9 refs.

**081644 DSC OF  $\gamma$ -IRRADIATED ULTRA-HIGH MOLECULAR WEIGHT POLYETHYLENE AND HIGH DENSITY POLYETHYLENE OF NORMAL MOLECULAR WEIGHT.** The melting and the crystallization of  $\gamma$ -irradiated (doses: 0-6 Mrad) ultra-high molecular weight nascent polyethylene (UHMWPE) and high density nascent polyethylene with normal molecular weight (NMWPE) were investigated by DSC (differential scanning calorimetry). The heat of melting of the nascent UHMWPE (DSC degree of crystallinity, respectively) increases up to a dose of 3 Mrad, after which it slightly decreases. The heat of the second melting of UHMWPE and of the first and second melting of NMWPE increases slightly up to a dose of 3 Mrad, after which it does not change. The X-ray degree of crystallinity of the nascent non-irradiated and irradiated polymers was  $0.62 \pm 0.02$ . The calorimetric crystallinity was compared to the X-ray one. The results show that radiation does not affect the polymer crystallinity, but influences the thermodynamic heat of melting. (Edited author abstract) 19 refs.

**081645 NETWORK PROPERTIES OF MIXTURES OF PROTONATED AND DEUTERATED POLYETHYLENE.** Mixtures of protonated and deuterated polyethylene were irradiated in the melt. The degree of crystallinity, the degree of crosslinking, as well as the enthalpy and the melting point were determined. No significant differences in the degree of crosslinking between protonated and deuterated chains were found. The mass specific entropy of the uncrosslinked samples remained constant and independent of the deuterium concentration. For the crosslinked samples, a netpoint entropy was postulated. A weaker Van der Waals interaction could explain the decrease in melting temperature by deuteration (for weakly crosslinked samples). (Author abstract) 11 refs.

**081646 MOEGELICHKEITEN EINER ECHTZEIT-KONSISTENZANALYSE ZUR STRAHLENEXPOSITION VON POLYETHYLEN.** [Possibilities of a Real-time State-of-Matter Analysis during Irradiation of Polyethylene]. Plastics used in nuclear engineering applications are subject to special radiation-resistance requirements. The effects of high energy radiation on material characteristics are studied, and a procedure, independent of time of exposure, is suggested that allows predictions to be made about the effect of radiation on polyethylene. From this, the possibilities of a real-time state-of-matter analysis and the reliable prediction of the utility of polyethylene in nuclear engineering practice are developed. (Author abstract) 12 refs. In German and English.

Brauer, Gerhard (Technischen Univ Dresden, Dresden, East Ger); Hertle, Wolfgang. *Kunstst Ger Plast* v 78 n 5 May 1988 p 424-426.

**081647  $^{13}\text{C}$  CP-MAS NMR STUDY OF IRRADIATED POLYETHYLENE.** Solid-state  $^{13}\text{C}$ -NMR was used to analyze several polyethylene samples, irradiated at room temperature with gamma rays in vacuum or with electrons in air up to a maximum dose of 200 Mrad. The

main observed events were the formation of methyl ends and interior double bonds (vinylenes), as well as the disappearance of the initial vinyl ends. No signals associated with 'H' or 'Y' crosslinks were found in any of the samples. The partitioning of methyl ends and interior vinylenes between the crystalline and noncrystalline regions was determined only for the irradiated ultrahigh-molecular-weight polyethylene (UHMWPE) samples. Although concentration of methyl ends in the crystalline regions was approximately half that in the noncrystalline regions, the vinylenes had very similar concentrations in the two phases. Although some evidence for both cis and trans vinylenes appears in the spectrum of the noncrystalline regions, only one configuration (trans) seems to exist in the crystalline regions. (Edited author abstract). 37 Refs.

**081648 CROSSLINKING OF POLYETHYLENE IRRADIATED IN A MULTILAYER SYSTEM.** Polyethylene films characterized by different thickness and crosslinking efficiencies were irradiated with 1.5 mev electrons at an average current density of 0.016 ma/cm<sup>2</sup>. The samples were in the form of film stacks with or without distance supports between the polymer layers. Some of the samples were irradiated in an N<sub>2</sub> atmosphere. The absorbed dose in a given polymer layer was estimated from the gel content. From the dose-gel dependence estimated for each polymer layer and the dose-depth dependence based on the literature data, the gel-depth and dose-depth curves were plotted. From the comparison of these curves with experimental data, it was concluded that the absorbed dose depends on the polymer film thickness and the presence or absence of the gas phase between polymer layers. (Edited author abstract). 10 Refs.

**081649 INFLUENCE OF IONIZING IRRADIATION IN AIR AND NITROGEN FOR STERILIZATION OF SURGICAL GRADE POLYETHYLENE FOR IMPLANTS.** The influence of the atmosphere and the applied dose during ionizing gamma radiation treatment on selected properties of ultra high molecular weight polyethylene (UHMWPE) have been investigated. A linear correlation between extinction coefficient and applied doses in air from 6 to 125 kGy was found, while oxidation was not linear with irradiation in nitrogen. Bacteria survival rate shows a necessary minimum dose of 15 kGy for assured sterility of the product. Post reaction of latent free radicals in UHMWPE created during irradiation has also been investigated after storage of UHMWPE-films in air and nitrogen at 21°C and in water at body temperature 37°C for up to nine months. Results show that the properties of UHMWPE after radiation-sterilization change depend on time, absorbed dose, atmosphere where irradiation took place and environment of storage. UHMWPE, which mainly crosslinks during irradiation, degrades by an oxidation process after sterilizing when stored in air and even more in water. So irradiation and storage in nitrogen before implantation in the human body is beneficial. (Author abstract) 23 refs.

## Reinforcing

**081650 INFRARED ANALYSIS AND IZOD IMPACT TESTING OF MULTICOMPONENT POLYMER COMPOSITES: POLYETHYLENE/EPDM/FILLER SYSTEMS.** Various multicomponent polyethylene/rubber/filler composites have been characterized by diffuse reflectance infrared spectroscopy (DRIFT) and notched Izod impact testing. The fillers used were an oxidized silicon powder and calcium carbonate. The rubbers were ethylene propylene diene (EPDM) rubber

and a maleic anhydride grafted EPDM (EPDM-MA). DRIFT is useful for investigating the structure of these multicomponent composites on the molecular level. The Izod impact testing shows that impact properties of both the oxidized silicon powder and calcium carbonate composites are improved by rubber addition. The use of EPDM-MA results in greater improvement than EPDM. (Edited author abstract) 16 refs.

## Rheology See Also POLYMERS—Rheology.

**081651 ROLE OF SLIP ADDITIVES IN BLOWN FILM EXTRUSION OF LOW DENSITY POLYETHYLENES.** Slip additives are low viscosity additives, which are compounded to modify the surface properties of polyolefin films and reduce the friction coefficient of the films. In this study, the effects of the slip additives on the rheology of low density polyethylene resins and the mechanical, optical and surface characteristics of blown films were investigated. It is determined that the slip additive remains dispersed in the matrix during flow through the capillaries. At relatively high concentrations the slip additive adversely affects some of the ultimate film properties including tensile strength and haze. (Author abstract) 9 refs.

**081652 RHEOLOGICAL CHARACTERISTICS, THERMODYNAMICS, AND MORPHOLOGIES OF POLYETHYLENE BINARY BLENDS.** Steady and dynamic melt viscoelasticity, thermodynamics and morphologies were investigated for linear/linear, branched/branched and linear/branched polyethylene blends. Elastic parameters such as the first normal stress difference ( $P_{11}-P_{22}$ ) and storage modulus ( $G'$ ) have large positive dependence on blend composition and show much higher values than those calculated from the following mixing rule which is valid for the linear/linear and branched/branched polyethylene blends at a constant shear rate. The deviation from this mixing rule is sensitive to shear rate in case of linear/branched polyethylene blends. The Flory-Huggins interaction parameter which is calculated from melting temperature depression suggests these blends to be miscible. (Edited author abstract) 22 refs.

**081653 RHEOLOGICAL PROPERTIES OF POLYETHYLENE MELTS FILLED WITH METAL- AND CARBON-FIBER.** The rheological properties under steady shear flow were examined for polyethylene melts filled with one of three metal fibers (two aluminum fibers of different fiber length and a 6-4 brass fiber) or one carbon fiber. For these four kinds of melts, shear stress and viscosity increased with the increase of fiber content and aspect ratio; large changes were found at lower shear rate. Similarly, relative viscosity and yield stress also increased, but the relative viscosity decreased with the increase of shear stress. An empirical equation of the relative viscosity considering fiber volume fraction and average aspect ratio was discussed. The first normal stress difference of the metal fiber dispersed systems became slightly larger than that of polyethylene matrix at a constant shear rate, while the effect of fiber content was extremely small. That of the carbon fiber system, however, increased with the increase of fiber content. (Author abstract) 18 refs. In Japanese.

## Shrinkage

**081656 HEAT SHRINKING BEHAVIOUR OF  $\gamma$ -RADIATION CROSSLINKED POLYETHYLENE.** Heat shrinking material of  $\gamma$ -radiation crosslinked polyethylene is widely used for various application in industry. In this study, DSC, TMA, WAXD and density measurement techniques were used to investigate the influence of MI and thermal history of LDPE on the effectiveness of network formation. Based on the results of heat stretching and heat shrinkage tests, it is found that the formation of a network as perfect as possible is indispensable to the irradiated material if good heat shrinkage property is desired. To this end, quenching technique and polyethylene with appropriate MI must be used so that an effective radiation effect will be obtained with a minimum amount of radiation dose. In spite of that the mechanical property of the irradiated polyethylene in the rubbery state is basically in agreement with the classical expression of the theory of high elasticity, only about 90% shrinkage can be reached. Besides, the heat shrinkage temperature  $T_s$  and the % shrinkage  $S$  are both related to the radiation dose. (Author abstract) 13 refs.

## Solutions

**081657 SOLUTION PROPERTIES OF POLY(ETHYLENE OXIDE) AS DETERMINED BY VISCOMETRIC MEASUREMENTS IN AQUEOUS SALT SOLUTIONS.** The properties of dilute solutions of poly(ethylene oxide)(PEO) in aqueous salt solutions are studied by measurements of intrinsic viscosity in theta and nontheta solvents. The unperturbed dimensions in various salt solutions were found larger than those in pure water. These results are attributed to a change in the polymer hydration sheath, in the gauche-trans equilibrium in the PEO chain in aqueous solutions, and in the water structure because of the added salt. Also, for carboxylic anions, similar behavior is expected due to the interaction of the ether oxygens of PEO with the weak acids through hydrogen bonding. (Edited author abstract) 36 refs.

**081658 INTERPRETATION OF INTRINSIC VISCOSITY/TEMPERATURE DATA FOR SOLUTIONS OF POLY(PHENYL ACRYLATE) AND POLY(ETHYLENE OXIDE).** Measured intrinsic viscosities ( $[\eta]$ ) at several temperatures ( $T$ ) within the interval

280-350 K have been found to increase with T for solutions of poly(phenyl acrylate) (PPA) in ethyl lactate. A decrease of  $[\eta]$  with T was observed for aqueous solutions of poly(ethylene oxide) (PEO) at several temperatures within the range 276-358 K. The results have been treated on the basis of eight excluded volume theories, among which the best consistency was afforded by those of M. Kurata-W.H. Stockmayer-A.J. Roig, M. Fixman, and W.H. Stockmayer. (Edited author abstract) 29 refs.

**081659 SEPARATION OF AQUEOUS SOLUTIONS OF POLYETHYLENE GLYCOL BY ULTRAFILTRATION.** Effect of concentration (2.0-60.0 kg/m<sup>3</sup>) of polyethylene glycol with molecular weight 40,000 on the separation of its aqueous solutions by a UAM-500 membrane at pressures of 0-500 kPa is investigated. It is shown experimentally that there is a significant increase in rejection and a decrease in bulk flow on an increase in polymer concentration. It is suggested that the increase in rejection in the investigated pressure range is due principally to leveling of the transmembrane flow orienting the macromolecules. (Author abstract) 7 refs.

**081662 MEASUREMENT OF THE DEGREE OF CRYSTALLINITY OF POLYETHYLENE WEAR DEBRIS BY MEANS OF RAMAN SPECTROSCOPY.** The Raman spectroscopic method for measuring the degree of crystallinity of polyethylene, developed by Strobl and Hagedorn and by Glotin and Mandelkern, has been applied to the wear debris arising from a continuous dry friction experiment which consisted of friction of high density polyethylene (HDPE) on glass. The analytical method was first tested on two reference HDPE samples having a known degree of crystallinity. The degree of crystallinity of the wear debris is higher than that of the initial non-rubbed material (HDPE,  $M_w = 4 \cdot 10^6$ ). The results are consistent with the conclusions of a previous tribological and rheological study. (Author abstract) 7 refs.

**081663 CARBON-13 NMR STUDY OF THE SOLID-STATE PHOTOCHEMISTRY OF POLY-(ETHYLENE-co-CARBON MONOXIDE).** The structure of an (E/CO) copolymer (1.4 wt% CO) has been studied by 50.3-MHz carbon-13 NMR spectroscopy. With model compounds, assignments of new structures and previously undetected products of photodegradation and photooxidation in the solid state were made. About 4% of the CO groups were accounted for as ethyl ketones with the remainder being randomly distributed along the polymer backbone chain. Evidence is presented for the formation of cis, trans-cyclobutanols, which have not been detected previously in the solid-state irradiation of ketone-containing polymers. A novel  $\alpha$ -branched ketonic structure was also found. (Edited author abstract) 40 refs.

**081664 EFFECT OF POST-IRRADIATION STORAGE CONDITION ON THERMOLUMINESCENCE FROM ULTRA-HIGH MOLECULAR WEIGHT POLYETHYLENE.** The effect of post-irradiation storage conditions such as liquid nitrogen (LN), saline solution at 37°C, and a dry atmosphere at RT on thermoluminescence (TL) from ultra-high molecular weight polyethylene (UHMWPE) has been investigated. A broad TL glow curve with peaks near 140 and 220°C was observed from the samples stored in LN. In the TL from the samples stored in saline solution or a dry atmosphere, the 140°C peak disappeared and a new peak near 240°C appeared. Electron spin resonance (ESR) measurements suggest that oxygen diffusion and subsequent quenching of free radicals (alkyl type) are the major cause of the disappearance of the 140°C peak, and that the thermal decay of the more stable free radicals (allyl type) produces glow peaks near 220 and 240°C. (Author abstract) 3 refs.

## Stability

**081665 STABILIZATION OF SELF-EXTINGUISHING TALC-FILLED POLYETHYLENE.** The investigation was carried out on a filled composition of 115-73 base type consisting of the following components (mass %): low-density polyethylene (LDPE) type 12002—200, 70; talc filler type A, grade 1, 20; fireproofing agents (antimony oxide + chlorinated paraffin), 5 of each. The following substances were introduced as stabilizers into the filled compositions: Tinuvin 326 (5-chloro-2-(3-hydroxy-3-tert-butyl-methylphenyl) benzotriazole) and 'oxaphenamide' (p-hydroxyphenylsalicylamide). Experiments show that the optimal stabilizer concentration, found by mathematical design of experiments ensures protection of talc-filled self-extinguishing LDPE during aging. The action of the mixture is not additive in comparison with the individual stabilizers. 7 refs.

**081669 INVESTIGATION ON THE LONG-TERM BEHAVIOR OF POLYETHYLENE AND POLY(VINYL CHLORIDE) UNDER STATIC LOAD.** The long-term behavior of high density polyethylene (HDPE) and poly(vinyl chloride) (PVC) under static mechanical load is investigated. The long-term behavior is determined as a function of stress and temperature. The applicability of the equation proposed by the authors which describes the dependence between the time-dependent failure, stress, and temperature of the two polymers is examined. The equation, derived from theoretical considerations, represents a modification of the Arrhenius equation for the chemical reaction rate. It is found that there is a complete agreement between the experimentally determined long-term behavior of PVC and HDPE and that calculated by the equation over the whole examined range of temperatures and stresses. ## Structure

**081670 EFFECT OF OXIDATION ON THE DYNAMIC AND STRUCTURAL PARAMETERS OF ORIENTED POLYETHYLENE IN THE DEFORMED STATE.** ESR spectroscopy using a radical probe and X-ray analysis have been employed to study the behavior under a load of oriented HDPE samples with narrow and wide MD first oxidized with an ozone-oxygen mixture. Loosening of the amorphous phase on reversible loading of the polymer films increases with rise in the degree of oxidation. The elasticity modulus E in the initial stage rises but falls for deeper degrees of oxidation. For oxidation of short duration no appreciable changes were found in the orientation; for longer oxidation times the orientation considerably diminishes. Oxidation leads to a sharp increase in the correlation time of the radical-probe. (Author abstract) 14 refs.

**081672** CHANGES IN THE VARIOUS ELEMENTS OF THE STRUCTURE OF POLYETHYLENE INDUCED BY IONIZING RADIATIONS (AS REVEALED BY DIFFERENTIAL SCANNING CALORIMETRY). The DSC (Differential Scanning Calorimetry) method has been used to measure the heat capacity at 100-430 K of linear and branched PE exposed to irradiation with fast electrons (5-700 Mrad). The changes in the various elements of the unordered regions (four regions of relaxation) and the radiation stability of the PE crystallites have been investigated. The authors demonstrate the specific influence of irradiation in each case due to the prevalence of crosslinking of portions of the chains with sufficient segmental mobility and the prevalence of the processes of degradation in conditions of 'suppressed' mobility. Sharply marked dependence of the radiation stability of the crystallites of PE on its prehistory was found. (Edited author abstract) 31 refs.

**081673** PREDICTION OF POLYMER CRYSTAL STRUCTURES AND PROPERTIES. POLYETHYLENE AND POLY(OXYMETHYLENE). Molecular mechanics is used to calculate in a unified manner, from transferable conformational energy functions, the packing parameters and energy, vibrational dispersion curves, heat capacity, and thermodynamic functions, elastic constants, and refractive indices of polyethylene (PE) and poly(oxyethylene) (POM). PE was chosen as a 'standard' to illustrate the method and POM because it occurs in two crystal forms occasioned by the effect of packing forces in distorting the intramolecular torsion angles and because its crystal properties are of interest. Compared to the free -GG- the helix in the orthorhombic form is under compression and that in the hexagonal form under tension. Good agreement between calculated and experimental structures was found. (Edited author abstract) 41 refs.

**081676** EFFECTS OF CHAIN STRUCTURE AND NETWORK CONSTITUTION ON SEGMENTAL ORIENTATION IN DEFORMED AMORPHOUS NETWORKS. Segmental orientation in deformed networks is analyzed in terms of configurational properties of constituent chains and of the network structure. Configurational evaluation by using the rotational isomeric state approximation with the polyethylene chain as an example shows that orientation depends strongly on (i) the direction of the investigated label relative to a chain bond, (ii) chain length, (iii) label location along the chain, (iv) configurational perturbations due to presence of a label along the chain, and (v) polydispersity. A molecular model of the network is required for the analysis of the effect of network constitution on segmental orientation. The constrained junction theory of rubber elasticity is employed to estimate the contributions to segmental orientation from the network structure. (Author abstract) 20 refs.

## Surface Properties

**081679** SURFACE LAYER OF FIBRILLAR MATERIALS OF HIGH MOLECULAR WEIGHT POLYETHYLENE. Linear polyethylene of high molecular

weight formed micro-fibrils when it was crystallized above the melting point under suitable stretching. The fibrils thus obtained have circular cross-section and even surface. The changes of surface structure of these fibrils by heat treatment were investigated by means of electron microscopies, differential scanning calorimetry, and X-ray diffractions. It was found that the crystals on a surface layer of the high oriented fibrils grew in the direction parallel to the oriented direction, while the crystallites of lowly oriented fibrils disordered with decreasing in the rate and ratio of stretching. In a surface layer of these low oriented fibrils, unevenness owing to many crystallites was observed. It is concluded that the larger surface area on this fibril resulted from the unevenness of irregular crystallites in the surface layers. (Edited author abstract) 13 refs. In Japanese.

## Testing

**081681** ETUDE COMPARATIVE DU COMPORTEMENT SOUS TENSION CONTINUE, DE DEUX TYPES DE POLYETHYLENE PAR LA METHODE DE L'ONDE DE PRESSION. [Comparative Study of the Behavior of Two Polyethylene Types under DC Voltage by the Pressure Wave Method]. In order to develop extruded high voltage dc cables it is necessary to improve the understanding of charge storage and transport phenomena occurring in insulators such as polymer materials, when they are submitted to high dc voltages. A comparison of the behavior of two types of polyethylene, LDPE and XLPE, is presented. This study is based on the measurement, using the pressure wave propagation method, of the evolution of charge distribution in samples under electric stress. Important characteristics of these two materials are obtained, such as the internal field distribution, its distortion as compared to the applied field, and the localization of the charges responsible for these effects. For the materials under test, some regions of the samples are submitted to a field exceeding the applied one by 80%. Nevertheless, the localization of the space charges observed in some situations indicates that there is no particular risk during a reversal of the polarity of the applied voltage. (Author abstract) In French. 5 refs.

**081682** REOLOSKO ISPITIVANJE HDPE-A U OSLOVIMA DINAMICKI NAMETNUTIH DEFORMACIJA. [Rheological Examination of HDPE Under Conditions of Mechanically Induced Deformations]. Results are reported of testing a series of homo- and copolymers of high density polyethylene, mass flow rate 0.20...0.30 g/10 min, density 0.938...0.965 g/cm<sup>3</sup>, and molecular weight distributions 3...30. The tests were made by means of a rheological measurement instrument, with periodically imposed deformations. The determined val-

ues were the shear modulus, storage and loss,  $G'$ ,  $G''$  and complex viscosity as a function of oscillation frequency. On the basis of rheological measurements, it is possible to establish their importance for the determination of the type of material best suited to individual processing techniques. At the same time, statistical processing of rheological parameters establishes a correlation between the shear modulus and distribution of molecular weights. (Edited author abstract) 3 refs. **081683 WATER TREEING TEST USING THE WATER NEEDLE METHOD: THE INFLUENCE OF THE MAGNITUDE OF THE ELECTRIC FIELD AT THE NEEDLE TIP.** The initial growth kinetics of water trees in polyethylene is measured for different values of the radius of curvature of the needle tip and for different applied voltages. The initial propagation rate is shown to be determined by the magnitude of the electric field at the needle tip, except at its highest values. The local electric field at the solution/polymer interface or in its vicinity plays an essential role in the growth mechanisms of water trees; it determines the initial propagation rate up to values of about 100 to 300 V/ $\mu\text{m}$ . Above these field values the water tree growth is found to be controlled by slower processes, e.g., the migration of the liquid through the polymer. These results are used in discussing some experimental conditions which are required to get reproducible results in water needle tests. 6 refs.

**081684 CALORIMETRIC INVESTIGATIONS OF THE SYSTEM HIGH MOLECULAR WEIGHT POLYETHYLENE OXIDE-WATER.** The binary system PEO-water has been studied by differential microcalorimetry over the temperature range 150-380 K. From analysis of the experimental findings on the character of the change in the temperature and concentration functions of the specific heat capacity of the system and the thermodynamic characteristics of its components in the regions of phase conversions and the kinetic transition (vitrification-softening) an explanation is given for the exothermal transition manifest in the system at a temperature above softening. The presence of this transition is related to the ability of water to form a part of the secondary hydrate layer for vitrification at relatively low cooling and crystallization rates on subsequent heating. (Edited author abstract) 12 refs.

**Thermodynamics**

**081685 THERMODYNAMICS OF ISOTOPIC POLYMER MIXTURES: POLY(VINYLETHYLENE) AND POLY(ETHYLETHYLENE).** Binary mixtures of normal (protonated) and perdeuterated poly(vinylethylene), and of poly(ethylethylene), containing 50% by volume deuterated polymer, have been examined by small-angle neutron scattering (SANS). Evaluation of SANS data obtained between 26 and 100°C, using the RPA theory for binary polymer mixtures, reveals that both isotopic systems are characterized by a small positive Flory-Huggins segment-segment interaction parameter,  $5 \times 10^{-4} < \chi < 10^{-3}$ , and an upper critical solution temperature (UCST). This isotope effect primarily derives from the reduction in carbon-hydrogen bond length that results from substituting deuterium for hydrogen in nonpolar organic liquids. The authors conclude that nonideal mixing is a universal characteristic of deuterated and protonated polymers. (Edited author abstract) 31 refs.

**081686 COLLAPSE OF POLY(ETHYLENE OXIDE) MONOLAYERS.** Surface pressure  $\pi$  has been measured as a function of surface concentration for poly(ethylene oxide) (PEO) surface films, spread onto deionized water at temperatures  $T$  from 8 to 28°C. At fixed surface coverage, the temperature coefficient of surface pressure  $d\pi/dT$  was negative at submonolayer coverages and positive at higher surface coverages. This suggests, respectively, a peculiar increase and decrease of surface entropy with increasing surface coverage. A degree of ordering of water molecules with the PEO repeat unit in the surface layer is suggested as a reason for the negative value. These findings illustrate that a polymer monolayer should not in all respects be considered as two-dimensional. (Edited author abstract) 27 refs.

**081687 ROLE OF COUNTERFACE IMPERFECTIONS IN THE WEAR OF POLYETHYLENE.** A study was made of the effect of single imposed imperfections in stainless steel counterfaces on the wear of ultrahigh molecular weight polyethylene wear pins in linear reciprocating wear tests. The imperfections were in the form of either transverse or longitudinal scratches or single indentations, all generated by diamond markers. It was found that a single transverse scratch can increase the wear rate of the polymer to a remarkable extent; the major factor being the piled-up steel along the edge of the scratch. When the piled-up material was removed by remedial lapping, the wear rate returned to its initial value corresponding to the isotropic roughness of the undisturbed counterface. Longitudinal scratches yielded a less marked, yet recognizable, increase in the wear rate of the polyethylene. Single diamond indentations did not generate piled-up edges of steel and had little effect upon the wear rate of the polymer. The findings demonstrate the severe effect which simple imperfections on a hard counterface can have upon the wear of polymers. Even shallow transverse scratches can increase the wear rate by an order of magnitude. (Edited author abstract) 10 refs.

**081688 EFFECT OF ANNEALING ON FIBER STRUCTURE OF ULTRA-HIGH MOLECULAR WEIGHT POLYETHYLENE.** Ultra-high molecular weight polyethylene (UHMWPE) was drawn at 150 °C (above melting point) and immediately quenched at 0°C. Samples of film were annealed at various temperatures at constant length. The fine structures were studied by wide- and small-angle X-ray analyses. Crystallites with a-axis orientation predominated for the quenched film with a high draw ratio of 12, in which the so-called bi-component crystallization might occur: most crystals were folded chain type, with a small number of extended chain crystals. The crystallites become rotated by thermal stress at annealing temperatures above 80°C. The crystallites took the c-axis orientation by annealing above 130°C. No large change in the crystallite length  $D_{002}$  by annealing was observed. The voids between fibrils for quenched film decrease with increasing of annealing temperature; in other words, fibrils pack more closely. (Edited author abstract) 32 refs. In Japanese.

**081689 EFFECT OF HIGH ENERGY RADIATION**

**ON THE STRESS-REELAXATION OF ULTRA-HIGH MOLECULAR WEIGHT LINEAR POLYETHYLENE.** Stress-relaxation behavior was studied in ultra-high and normal molecular weight linear polyethylenes (UHMWPE and NMWPE) as a function of radiation dose over the range 0-128 Mrad. Irradiation up to 16 Mrad raises the crystallinity in both types of PE, as demonstrated previously, and thus increases the initial modulus. Also, the initial modulus of NMWPE is higher than that of UHMWPE because the former has a higher crystallinity. To eliminate the effect of this initial difference on relaxed stress, the stress-relaxation data were normalized with respect to the initial stress and plotted as the fraction, retained stress after time  $t$ /initial stress. The normalized plots show no significant difference between NMWPE and UHMWPE in their stress-relaxation behavior. (Edited author abstract) 21 refs.

**081690 INVESTIGATING THE THERMOFORMABILITY OF UHMW-POLYETHYLENE.** The formability of UHMW-polyethylene is examined by combining the concept of uniaxial testing at various temperatures at constant rate or constant load with a standardizable thermoforming method that employs molds with variable geometry. Preliminary results analyze and define processing parameters such as: heating time, vacuum pressure, and draw ratio, among others. Finished material properties of the resultant thermoformed parts are presented. (Author abstract) 5 refs.

**081691 SUPERDRAWING OF ULTRAHIGH MOLECULAR WEIGHT POLYETHYLENE. 1. EFFECT OF TECHNIQUES ON DRAWING OF SINGLE CRYSTAL MATS.** Single crystal mats of ultrahigh molecular weight polyethylene (UHMW-PE) have been uniaxially drawn by three techniques: solid-state coextrusion, tensile drawing, and the combination of the two. The drawability and the resultant structure and properties of superdrawn films were found to be sensitive to drawing technique. Tensile drawing was markedly influenced by the coherency of the mats and the draw temperature and rate. Draw ratios (DR) over 200 at  $\geq 90^\circ\text{C}$  under controlled rates have been achieved for coherent mats. Effective draw was not possible for less coherent mats and for all drawn at  $\leq 60^\circ\text{C}$ . (Edited author abstract) 41 refs.

**081692 DYNAMIC MECHANICAL STUDIES ON CRYSTAL DISPERSION USING ULTRADRAWN POLYETHYLENE FILMS.** The anisotropy of crystal dispersion was investigated by use of ultrahigh molecular weight polyethylene ( $M_v = 6 \times 10^6$ ) gel films which were prepared by gelation/crystallization from solution. The temperature dependence of the complex dynamic modulus was measured in the frequency range from 0.1 to 100 Hz, using undrawn and drawn gel films with various draw ratios up to 400. Superposition is realized by a combination of horizontal and vertical shifts resulting in apparent master curves of the storage and loss modulus functions. The Arrhenius plots of log shift factor versus the reciprocal of the absolute temperature indicates that there exist two mechanical dispersions corresponding to the  $\alpha_1$  and  $\alpha_2$  mechanisms, for drawn specimens whose draw ratios are lower than 100. (Edited author abstract) 40 refs.

**081693 EFFECT OF COUNTERFACE SURFACE ROUGHNESS ON THE WEAR OF UHMWPE IN WATER AND OIL-IN-WATER EMULSION.** This paper examines the effect of the type of lubricant and the counterface surface roughness on the wear of ultrahigh molecular weight polyethylene (UHMWPE). A reciprocating sliding wear rig was used with UHMWPE sliding against AISI 431 at an average speed of 0.25 m/s. The contact pressure was 10 N/mm<sup>2</sup>. Tests were conducted in water and in a 5% oil-in-water emulsion (5:95). The results of the tests in water showed that the logarithm of the specific wear rate is proportional to the surface roughness. The results of the tests in 5:95 showed that there is a significant transition in specific wear rate at a surface roughness of approximately 0.35  $\mu$ m. At surface roughnesses less than 0.35  $\mu$ m the specific wear rate in 5:95 is considerably lower than the specific wear rate in water, while at surface roughnesses greater than 0.35  $\mu$ m the specific wear rate in 5:95 approaches that in water. (Edited author abstract) 9 refs.

**081694 COEXTRUSION DRAWING OF REACTOR POWDER OF ULTRAHIGH MOLECULAR WEIGHT POLYETHYLENE.** Certain nascent polymers have been shown to have unusual thermal and morphological properties that are irretrievably lost once the polymer has been melted or otherwise reduced to the isotropic state. We show further that nascent ultrahigh molecular weight polyethylene 'reactor powder' exhibits a remarkable ductility when uniaxially drawn by coextrusion techniques after initial compaction in film form at 110°C. When drawn at a temperature of 110°C, draw ratios of 56 have been obtained, resulting in an enhanced tensile modulus of 58 GPa. Thermal analyses and dynamic mechanical measurements were also made towards understanding the initial and final morphologies. (Author abstract) 17 refs.

**081695 SINGLE-CRYSTAL-LIKE ORIENTATION OF ULTRAHIGH-MOLECULAR-WEIGHT POLYETHYLENE BY UNIAXIAL STRETCHING.** Dried gel film of ultrahigh-molecular-weight polyethylene (UHMW PE) can be drawn to 370 times its original length at 135°C. Single-crystal mats and dried gel film of UHMW PE develop double orientation despite uniaxial stretching. This is unique for preferentially oriented UHMW PE systems. To elucidate the origin of this single-crystal-like orientation, precursors with different aspect ratios were prepared and drawn uniaxially. The degree of double orientation was measured by infrared spectroscopy. The origin of single-crystal-like orientation seems to reside in the necking region. The stacked lamellar structure is transformed into a fibrillar structure in a two-dimensional fashion. This condition is easily provided when UHMW PE single-crystal mat or dried gel film is drawn uniaxially. A draw ratio of 40 and aspect ratio of 40 are the optimal conditions to obtain a doubly oriented structure from UHMW PE single-crystal mat or gel film at 135°C. (Author abstract) 18 refs.

**081696 INFRARED MICROSPPECTROMETRIC STUDY OF THE THERMAL HISTORY OF FUSION WELDING OF POLYETHYLENE.** Thermal history of a polyethylene-welded assembly has been determined by measuring the crystallinity via absorbance ratio ( $R_{OD}$ ) measurements. Fourier transform infrared microspec-

trometry has been used because it allows a space-localized analysis within a diameter of 200  $\mu$ m. A linear relation between  $R_{OD}$  and local crystallinity has been obtained using reference samples for calibration. Samples were calibrated by differential thermal analysis and density measurements. This relationship and the simulation of the various thermal treatments by calorimetric analysis allow us to characterize the different phases of the thermal history during the welding experiment. ## X-Ray Analysis

**081697 TIME-RESOLVED SAXS ON CRYSTALLIZATION OF A LOW-DENSITY POLYETHYLENE/HIGH-DENSITY POLYETHYLENE POLYMER BLEND.** In this paper, we report our time-resolved SAXS patterns of a blend of low-density polyethylene (LDPE) and high-density polyethylene (HDPE) and of the respective homopolymers. It is concluded that the fine structural changes during the early stage of crystallization, observed through SAXS with synchrotron radiation, suggest the following clues: The single Bragg reflection does not necessarily mean that the two components have cocrystallized to form a single lamella structure, as has been interpreted previously. The observation could be interpreted as a separation between the two (LDPE/HDPE) components on an interlamella scale. 13 refs.

**081698 POSITIVE PHOTOREACTIVE POLYIMIDES. II. PREPARATION AND CHARACTERIZATION OF POLYIMIDE PRECURSORS CONTAINING  $\alpha$ -(2-NITROPHENYL)ETHYL ESTER SIDE CHAINS.** The monomers were derived from pyromellitic dianhydride and  $\alpha$ -(2-nitrophenyl)ethanol, which was prepared by selective reduction of 2-nitroacetophenone. Polyimide precursors were synthesized by an interfacial polycondensation technique. Their thermal properties in nitrogen were studied by dynamic thermogravimetry. The photorearrangement of 2-nitrobenzyl ester having a methyl group at the  $\alpha$ -position compared to that of the unsubstituted ester was investigated by infrared spectrophotometry. The polymers obtained in this study gave a high proportion of photorearrangement to show high sensitivity. (Edited author abstract)

## Additives

**081700 IMIDE SILANES: ADHESION PROMOTERS FOR POLYIMIDES.** The investigation of adhesion promoters prepared by the reaction of amino-functional silanes with dianhydrides (or diester-diacid chlorides) of tetracarboxylic aromatic acids is reported. The new coupling agents, designed to exhibit superior thermo-oxidative stability were applied under conditions determined from kinetic studies of hydrolysis and condensation reactions, and their coupling effectiveness for polyimides was evaluated by peel tests. For a wholly aromatic imide silane (CA-25), adhesion retention after prolonged exposure to elevated temperature was far greater than obtained with adhesion promoters previously evaluated in polyimide systems. (Author abstract) 15 refs.

## Adhesion

**081701 ADHESIVE INTERFACE INTERACTIONS BETWEEN PRIMARY ALIPHATIC AMINE SURFACE CONDITIONERS AND POLYAMIC ESTER POLYIMIDE RESINS.** The interface reactions of 3-aminopropyltriethoxysilane treated surfaces, with a polyamic alkyl ester/polyimide resin formed from pyromellitic dianhydride and oxydianiline, were defined by Fourier Transform Infrared (FTIR) analysis on the surface layers of germanium internal reflection plates. Adhesion between these interfacial layers is the result of chemical bonding, which apparently proceeds through initial amide formation between the amino function of the silylated surface and the alkyl ester group present in the polyamic ester. Heating results in diamide formation by a second alkyl, surface-bound amine displacing the aromatic polymer amine. Heating the more stable dialkyldiamide to 300°C imidizes both the polymer and the interfacial region, producing a strong laminate composite. Polymer scission at the aromatic amide linkages occurs in this adhesion process, bonding surface-bound alkyl amines to one end of a shortened polymer chain. (Author abstract) 2 refs.

**081703 SCREEN-PRINTABLE POLYIMIDE COATING FOR SILICON WAFERS.** A new surface passivation technology, based on a unique screen-printable polyimide coating combined with a high precision, screen-printing machine is described. Discussion is focused on the physical and performance characteristics required of the printable polyimide for maximum protec-

tion of the device, and the processing characteristics (both material and equipment related) necessary to implement this new technology in production.

Kulesza, Frank W. (Epoxy Technology Inc, Billerica, MA, USA); Estes, Richard H.; Spanjer, Keith. *Solid State Technol* v 31 n 1 Jan 1988 p 135-139.

**081704 PATTERN GENERATION IN POLYIMIDE COATINGS AND ITS APPLICATION IN AN ELECTROPHORETIC IMAGE DISPLAY.** Direct photo-patterning of polyimide (PI) films was done in two ways, both based upon the modification of the PI-precursor, the polyamic acid (PAA), by derivatives of methacrylic amide. In the first method, a photoreactive PAA is prepared by partially (25 mole percent) neutralizing PAA with N-(N',N'-dimethylamino) propylmethacrylic amide and completing the neutralization with methacrylic amide (75 mole percent). In the second method, the PAA is esterified, e.g. with N-hydroxyethyl-N-methylmethacrylic amide, through its isourea derivative. The modified PAAs are processed like conventional negative photoresists. In the first method, the photopolymer formed by selective UV exposure is bound to the PAA by intermolecular complexation, causing insolubility in the developer. The second method, which was investigated only qualitatively, provides crosslinked patterns. In both cases a pure PI film is left upon imidization at 350°C. The first method proved to be well-suited to making the potential well structure in an electrophoretic image display. (Edited author abstract). 20 Refs.

**Blending** See Also AROMATIC POLYMERS—Blending; POLYMERS—Spectroscopic Analysis.

**081705 HIGH TEMPERATURE POLYIMIDE BLENDS.** In a continuing effort to synthesize polymers that are readily processable and that exhibit state-of-the-art characteristics, LARC-TPI (Mitsui) and polyimidesulfone (PISO<sub>2</sub>) were blended and subjected to a limited melt flow and thermal properties characterization. Mitsui Toatsu of Japan, working under a licensing agreement with NASA, synthesized an imidized version of LARC-TPI molding powder that exhibited an extraordinarily high level of softening when heated to 300°C. Subsequently, a study of the calorimetric and rheological properties was accomplished by NASA-Langley on that material. The thermoplastic polyimidesulfone that possesses processability similar to polysulfones and the solvent resistance of the polyimides was synthesized and characterized at NASA-Langley in the early 1980's. (Author abstract) 9 refs.

**081706 MISCIBLE BLENDS OF POLYBENZIMIDAZOLE AND A DIISOCYANATE-BASED POLYIMIDE.** The thermal and i.r. spectral properties of the blends formed from polybenzimidazole (PBI) and polyimide have been studied. Single, composition-dependent  $T_g$  values occur, indicating miscibility over the entire composition range. Because of the sensitivity of the glass transition to the thermal history, it is not possible to determine the onset, if any, of high temperature phase separation by thermal measurements based on  $T_g$  determination. However, the N-H stretching band of PBI shifts with composition; the shift is up to 50  $\text{cm}^{-1}$  and an estimate of the phase-separation temperatures was obtained by following the disappearance of the N-H stretching band shifts as a function of annealing temperature. The results suggest that this system displays lower critical solution type phase behavior. (Edited author abstract) 6 refs.

## Chemical Reactions

**081707 FT-IR ANALYSIS OF HIGH-TEMPERATURE SOLID-PHASE REACTIONS USING GC-IR SOFTWARE.** A method for following chemical reactions in polymers, using the GC-IR software on an FT-IR spectrometer and a high-temperature thermal cell, is discussed. The method reduces disk access time between the collection of each spectrum, allowing many more data points for kinetic experiments to be collected. The imidization reaction of polyimides above 200°C is given as an example. (Author abstract) 13 refs.

Snyder, Randy W. (IBM, Endicott, NY, USA); Sheen, C. Wade. *Appl Spectrosc* v 42 n 2 Feb 1988 p 296-298.

## Coatings

**081708 MODIFICATION OF POLYIMIDE COATINGS BY HIGH ENERGY ION BOMBARDMENT.** Exposure of 25- $\mu\text{m}$  films of polyimide and polyamideimide to high doses ( $> 10^{15}/\text{cm}^2$ ) of energetic ions (energy  $\geq 100$  keV) resulted in physical and chemical modification of the film surface. Cross-section microscopy revealed damaged layers extending beyond the projected ion range; conductivity in this damaged layer was found to be as high as  $10^3 \Omega^{-1} \text{cm}^{-1}$ . Surface conductivity was found to be a function of ion energy and dose, with an exponential energy dependence from 200 to 900 keV. The temperature dependence and thermal stability of the surface conductivity were determined. (Author abstract) 15 refs.

Zussman, M.P. (Westinghouse R&D Cent, Pittsburgh, PA, USA); Wood, S.; Scala, L.C.; Bartko, J.; Vincenz, A. *J Appl Polym Sci* v 35 n 8 Jun 1988 p 2183-2191.

## Crosslinking

**081709 ON THE CROSS-LINKING MECHANISM OF BENZOPHENONE-CONTAINING POLYIMIDES.** A group of fully imidized polyimides containing benzophenone as well as alkyl-substituted biphenylmethane in the main chain were prepared. In these materials cross-links are formed on exposure to UV radiation through hydrogen abstraction by triplet benzophenone from the alkyl groups acting as hydrogen donors and subsequent coupling of the radicals so formed. The involvement of radicals in the process is supported by ESR spectra of the films under irradiation. The quantum yield of cross-linking is  $\phi = 0.027$ , and less than half of the benzophenone units in the solids are reactive. Even at the reactive sites the reaction probability is a mere 3%. (Edited author abstract) 23 refs.

## Curing

**081710 TIME-TEMPERATURE-TRANSFORMATION (TTT) CURE DIAGRAMS: RELATIONSHIP BETWEEN  $T_g$  AND THE TEMPERATURE AND TIME OF CURE FOR A POLYAMIC ACID/POLYIMIDE SYSTEM.** Glass transition temperatures ( $T_g$ ) were obtained vs. isothermal temperature ( $T_{\text{cure}}$ ) and time of cure for a polyamic acid/polyimide system. A time-temperature-transformation (TTT) isothermal cure diagram was constructed to include the time to vitrification and iso- $T_g$  curves. As for epoxies, the relationship between  $T_{\text{cure}}$  and the time to vitrification is S-shaped. Plots of  $T_g$  vs.  $T_{\text{cure}}$  show that solvent evaporation and chemical reaction are controlled by vitrification. (Author abstract) 11 refs.

Palmese, G.R. (Princeton Univ, Princeton, NJ, USA); Gillham, J.K. *J Appl Polym Sci* v 34 n 5 Oct 1987 p 1925-1939.

**081711 FTIR STUDIES OF PMR-15 POLYIMIDES.** Fourier-transform infrared spectroscopy (FTIR)

shows that during the curing of PMR-15 polyimide, formation of an anhydride intermediate occurs prior to the formation of polyamic acid, suggesting that its origin is the diester diacid starting material, as has recently been proposed by Johnston and coworkers. These results disagree with some previous literature reports that have attributed formation of the anhydride to a degradation pathway of polyamic acid and confirm the validity of a recently published paper by Johnston and coworkers. (Author abstract) 21 refs.

Garcia, Dana (BF Goodrich Co, Brecksville, OH, USA); Serafini, Tito T. *J Polym Sci Part B* v 25 n 11 Nov 1987 p 2275-2282.

**081712 CURING REACTION AND GLASS TRANSITION TEMPERATURE OF MALEIMIDE RESIN CONTAINING EPOXY GROUPS.** Investigation was made of the glass transition temperature ( $T_g$ ) and the curing reaction mechanism of a new maleimide resin containing epoxy groups. It was found that the  $T_g$  of the cured product depended on the reaction temperature and a good heat-resistant product could be obtained under appropriate conditions. This  $T_g$  was above 200°C. The reaction mechanism is discussed using measured activation energy and infrared spectra. The primary reaction changed at about 180°C. Both the addition of diamine to the double bond and epoxy group occurred below 180°C. The polymerization of double bonds of bismaleimide took place simultaneously with the above-mentioned two reactions above 180°C. (Author abstract) 7 refs.

## Degradation

**081713 INHOMOGENEOUS THERMO-OXIDATIVE DEGRADATION DURING HEAT AGEING OF ALIPHATIC POLYAMIDES IN BULK.** Changes of molecular mass (MM) and contents of COOH and  $\text{NH}_2$  end groups in blocks of aliphatic polyamides were studied during thermal ageing in the temperature range 50-160°C; it was shown that the largest changes of these characteristics occur in the 200-300  $\mu\text{m}$  thick surface layer in consequence of thermo-oxidative degradation. A satisfactory agreement was obtained between the calculated and experimental thickness of the oxidized layer. Together with thermo-oxidation, in PA-6 samples some additional condensation was also observed accompanied by an increase in MM which is most pronounced in the central part of the sample. (Author abstract) 13 refs.

Vasil'ev, V.A. (Research & Production Unit 'Plastmassy', USSR); Kudryavtseva, G.A.; Pavlov, N.N. *Polym Sci USSR* v 28 n 10 1986 p 2373-2379.

## Doping

**081714 ADDITIVE SELECTION CRITERIA FOR METAL-DOPED POLYIMIDES.** The use of metal dopants has been the focus of much activity, primarily aimed at enhancing the electrical properties of polymeric materials. A series of copper additives have been investigated for their suitability as potential dopants in polyimide films. In all instances where the additives meet the solvent and thermal decomposition requirements, good polymer films with reasonable thermal stability have been produced which suggests that they are useful criteria in dopant selection. 7 refs.

## Elasticity

**081715 DYNAMIC MECHANICAL PROPERTIES OF POLYAMIDOIMIDES BASED ON TRIMELITIMIDO-N-ACETIC ACID.** It was shown that a change in chemical structure of the amine fragment of a

polyamidoimide leads to broadening or splitting of the relaxation peak, which is explained by structural microheterogeneity of the polymer. It was established that PAI are characterized by high moduli elasticity, the values of which remain quite high for individual polymers at elevated temperature, and retain elasticity and high stability at low temperatures. (Author abstract) 6 refs.

**081716 ELASTICITY OF CRYSTAL LATTICE AND CHAIN RIGIDITY OF POLYIMIDE PM.** On the basis of X-ray diffraction data and simple geometrical considerations, chain conformations that can exist in the crystalline phase of polyimide PM have been analysed. It is demonstrated that a more folded conformation than the known trans-zig-zag is possible. Geometrical parameters and chain compliance were estimated from equations derived by T. Miyazawa. Formulae that relate the overall chain compliance, geometrical parameters, and elastic properties of individual constitutive units have been derived in analytical form. Contributions individual elements to the chain compliance have been estimated. (Edited author abstract) 9 refs.

## Electric Properties

**081717 EFFECT OF METAL HALIDES ON THE ELECTRICAL PROPERTIES OF POLYIMIDES.** This paper describes the effect of metallic salts, Sn(II), Hg(II), Co(II) chlorides, on the electrical properties of polyimide films derived from 3,3',4,4'-benzophenone tetracarboxylic acid dianhydride (BTDA) and 4,4'-diaminodiphenyl ether (E). The effect of temperature/field on the electrical conductivity of the films was studied. An ohmic/sublinear behavior in undoped film and a non-ohmic behavior at high field and temperature was observed in doped films. Dielectric characteristics ( $\epsilon$  and  $\tan \delta$ ) as a function of frequency and temperature were also investigated. (Edited author abstract) 18 refs.

Varma, I.K. (Indian Inst of Technology, Delhi, India); Saxena, Sneh; Tripathi, Anita; Varma, D.S. *Polymer* v 29 n 3 Mar 1988 p 559-565.

**081718 COMPARISON OF THE ELECTRICAL PROPERTIES OF POLYIMIDE FILMS CONTAINING SURFACE METAL OXIDE: COBALT OXIDE VS. TIN OXIDE.** In this paper, the thermal, electrical and spectroscopic data regarding anhydrous cobalt(II) chloride and tin(II) chloride dihydrate modified polyimide films is compared and contrasted. A more complete understanding of the various synthetic parameters which act to produce these interesting materials is also presented. Finally, the applicability of the model, which had been proposed for the  $\text{Co}_3\text{O}_4$  containing polyimides, to the tin oxide containing polyimides is evaluated. 32 refs.

## Electrochemistry

**081719 ELECTROCHEMISTRY OF THERMALLY CYCLIZED POLYIMIDE FILMS.** An electrochemical study of poly(4,4'-oxydiphenylene-pyromellitimide), better known as Kapton, was conducted. The cyclic voltammetric response of the thermally cyclized polymer in aqueous electrolytes shows two chemically reversible electron transfers. Electrochemical methods indicate the rate of charge propagation in this polymer is principally dependent upon mass transfer. Surprisingly, the investigation of this polymer in nonaqueous electrolytes showed exceedingly poor electrochemical behavior relative to the aqueous electrolytes. The difference between the electrochemistry of the polymer in aqueous vs. nonaqueous electrolytes is believed to be due to solvent effects on the electron

transfer properties rather than mass-transfer effects. (Author abstract) 25 refs.

**Film** See Also COATINGS—Physical Properties.

**081721 EVALUATION OF POLYIMIDE FILMS AS ADHESIVES.** A commercially available LARC-TPI film and an experimentally prepared film of LARC-TPI with 5 mol% of 4,4'-oxydianiline (ODA), designated as LARC-TPI/ODA in the paper supplied by Mitsui Toatsu Chemicals, Incorporated (MTCI), Japan, were evaluated as thermoplastic adhesive films for bonding Ti-6Al-4V. The LARC-TPI/ODA had been shown by MTCI to possess more flow than thermoplastic LARC-TPI and was, therefore, evaluated and compared to the LARC-TPI. Lap shear strength was used to evaluate the materials as adhesives. The mode of failure is also reported. (Edited author abstract) 11 refs.

**081722 MECHANICAL PROPERTIES AND TRANSITION TEMPERATURES OF A COMBINED POLYIMIDE FILM.** The use of pure polymeric materials has now decreased in industry due to the extensive use of composites, which combine the best properties of the individual components. For this reason, the evaluation of the mechanical properties of heterogeneous systems from the properties of the individual components is an especially important problem. An a priori evaluation of the set of mechanical characteristics and transition temperatures of a combined polyimide film (layered polymer-polymer composite) based on the corresponding parameters of the individual layers and their ratios was conducted in the present study. PM-1 and PM-4 films were prepared by the method of pouring lac on a solid support with subsequent heat treatment. The combined PM-414 film was prepared by layered pouring of the corresponding lacs. 10 refs.

Gurinovich, L.N. (Plastmassy Scientific & Industrial Assoc, Moscow, USSR); Kovriga, V.V.; Lur'e, E.G. *Mech Compos Mater* v 23 n 1 Jan-Feb 1987 p 123-128.

**081723 TEARING OF THIN POLYIMIDE FILMS.** Films of BTDA-ODA polyimide up to 58  $\mu\text{m}$  thick were torn at constant cross-head speed in 'trousers' tests. In common with previous results on polyolefins, the work of tearing was found to increase markedly with specimen thickness. A model for the increase, based on the volume of plastically deformed material adjacent to the crack plane, was found to be only qualitatively valid. The experimental slope of a plot of tearing energy (per unit area) against thickness was 70  $\text{MJm}^{-3}$ . Optical and scanning electron micrographs of torn films are discussed in regard to the modes of failure. (Author abstract) 12 refs.

**081724 SOLVENT-INDUCED LOCAL DEFORMATION ZONES IN POLYIMIDE FILMS ADHERED TO A RIGID SUBSTRATE.** Thin films of a polyimide (Ciba-Geigy XU293) adhered to rigid substrates devel-

oped special type of local deformation zones when immersed in xylene. These deformation zones were initiated because of the presence of the combination of xylene and the equi-biaxial tension resulting from the drying process. Their microstructure was strongly influenced by the local bonding to the substrate. In the bonded regions, the zones resembled a narrow trench containing deformed but unvoided material. In the unbonded regions, complicated fibrillar structure was observed in the much wider zones. Although they retained a smooth surface on the face in contact with the substrate in the bonded regions, the deformation zones released a significant amount of stress. The stress release was measured by a photo-elastic method and was found to be in excellent agreement with that calculated from the local thickness change assuming simple elasticity. Although not cracked, there were lines of weakness; after long soaking times the films cracked and delaminated along the defects. (Author abstract) 18 refs.

**081725 HIGH STRENGTH AND HIGH MODULUS AROMATIC POLYIMIDE/POLYIMIDE MOLECULAR COMPOSITE FILMS.** Recently we obtained high strength, high modulus aromatic polyimide films having a maximum modulus of 60 GPa by thermal imidization of cold drawn poly(amic acid) precursor films. The polyimides giving high modulus and high strength seem to have a rather rigid chemical structure, while the polyimides having a flexible structure do not give high strength and high modulus under the same processing conditions. In the present study, we report the preparation of molecular composite films of these strong, rigid aromatic polyimides embedded in a ductile matrix of flexible polyimides. 8 refs.

**081726 STRENGTH OF RUBBING WORKED ON POLYIMIDE FILMS FOR ALIGNING NEMATIC AND CHIRAL SMECTIC LIQUID CRYSTALS: CONTROLLING PRETILT ANGLES AND SOME ELECTROOPTIC PERFORMANCES OF LCDs.** The degree of work done on polyimide films in the rubbing process with a nylon fabric was detected and evaluated in terms of induced birefringence. Strong and weak rubbing (effecting two extremes) gave rise to the optical retardation of 1 degree and 0.1 degree, respectively, with a resolution of 0.1 degree. Generation of a pretilt angle of up to 10 degrees (even up to 30 degrees) for nematic liquid crystals was achieved by performing weak rubbing on a specially synthesized polyimide which was successfully used to fabricate supertwisted nematic liquid crystal displays. Fairly good bistability in a ferroelectric liquid crystal device was also obtained by weak rubbing. (Author abstract) 8 refs.

## Friction

**081727 FRICTION AND WEAR STUDIES OF A BISMALEIMIDE.** Bismaleimides are thermally stable thermosetting polyimides. They are brittle in nature, because of their high cross-link density, which can be reduced by certain chain extension reactions. The authors have previously studied the friction and wear properties of 4,4'-(bismaleimido) diphenyl methane. This compound has a high rate of wear. This paper discusses the friction and wear properties of a chain-extended product of 4,4'-(bismaleimido) diphenyl methane. Chain extension improves the wear characteristics of the bismaleimide, particularly at high loads. (Author abstract) 16 refs.

Feb 1988 p 27-30.

**081728 EFFECTS OF TEMPERATURE AND AMBIENT PRESSURE ON FRETTEING PROPERTIES OF POLYIMIDE.** In order to study the dependence of tribological properties of polyimide on the environment, the fretting properties of polyimide against SUS316L stainless steel were examined under a normal load of 14 N, a peak-to-peak slip amplitude of 80  $\mu\text{m}$ , a frequency of 16.7 Hz and  $10^5$  cycles by varying the temperature from 20 to 300°C and an ambient pressure in the range  $10^5$  -  $10^{-3}$  Pa. There were two distinct regimes of wear surface morphology dependent on temperature and ambient pressure. One was of an overall transfer layer, with a very smooth surface and some cracking, along with plate-like debris formed at pressures above 10 Pa at 20°C, and temperatures to 300°C at  $10^5$  Pa. The other regime was one of island transfer, an abraded surface and very fine wear debris formed at pressures below  $10^3$  Pa at 300°C, and temperatures to 300°C at  $10^{-3}$  Pa. (Edited author abstract) 17 Refs.

## Heat Resisting

**081729 THERMO-OXIDATIVELY STABLE CONDENSATION POLYIMIDES CONTAINING 1,1,1-TRIARYL-2,2,2-TRIFLUOROETHANE DIANHYDRIDE AND DIAMINE MONOMERS.** Nine new condensation polyimides containing the trifluorophenylthylidene linkage were synthesized by the amic-acid route. Several other polyimides, including some with the hexafluoroisopropylidene linkage, were also prepared as controls. Amic-acid solutions were characterized by determining their inherent viscosities prior to thermal conversion into polyimide films. Glass transition temperatures ( $T_g$ ), thermogravimetric analysis (TGA), and isothermal weight loss data (at 316°C, 371°C, and 371°C under 0.5 MPa air pressure) were obtained for the films. The films were pulverized into molding powders which, in turn, were thermally processed under pressure into neat resin discs. The discs were also characterized by  $T_g$ s and 316 and 371°C isothermal weight losses. The film study identified two new polyimides with  $T_g$ s greater than 371°C and two new polyimides with low rates of weight loss. (Edited author abstract) 3 refs.

## Heat Treatment

**081730 STRUCTURE AND PROPERTIES OF HIGHLY CRYSTALLIZED GRAPHITE FILMS BASED ON POLYIMIDE KAPTON.** Highly crystallized graphite films were prepared by heat treatment of carbonized polyimide films (Kapton) at temperatures of 2700 and 3050°C. Interlayer spacing  $d_{002}$  at room temperature and electrical resistivity, magnetoresistance and Hall coefficient at room and liquid nitrogen temperatures were measured. For the graphite films heat treated at 3050°C mean square mobilities were estimated from the magnetoresistance data at 1 T to be  $0.91 \text{ m}^2 \text{V}^{-1} \text{sec}^{-1}$  at room temperature and  $2.3 \text{ m}^2 \text{V}^{-1} \text{sec}^{-1}$  at liquid nitrogen temperature; the value at liquid nitrogen temperature corresponds to that for a pyrolytic graphite heat treated at 3200°C for 1 h (PG 3200). Magnetic field dependence of the Hall coefficient at liquid nitrogen temperature agrees well with that for PG 3200. Scanning electron micrographs show that the graphite films consist of grains of large crystallites, and grain size increases as the crystallinity of the material improves. (Edited author abstract) 7 Refs.

**Mechanical Properties** See Also AROMATIC POLYMERS—Mechanical Properties.

**081731 PROPERTIES OF POLYIMIDES.** Due to the stability of the imide group and aromatic molecular chains, polyimides distinguish themselves by a series of interesting properties. In spite of their high price these plastic materials are increasingly used in the electric and electronics industry, automotive industry, aeronautics and space travel, construction of plants and apparatus, nuclear engineering plants as well as in military engineering. Two-figure growth rates are to be expected within the next few years. The mechanical and tribologic properties as well as the behaviour at high temperatures are studied on a representative material of this plastic material class. (Author abstract) 8 refs. In German and English.

**081732 NOVEL POLYAMIDE-IMIDES.** A series of thermally stable, tough, linear polyimides containing amide linkages were prepared. These materials have potential as high temperature films and coatings as well as matrix resins in graphite reinforced structures. The new polyamide-imides were prepared by reacting a group of isomers of diaminobenzanilide (DABA) with 3,3',4,4'-benzophenonetetracarboxylic dianhydride (BTDA) to form the polyamide-acid with subsequent thermal conversion to the polyamide-imide (PAI). Four polymers were synthesized from unsubstituted amide diamines and two others from N-substituted amide diamines. The properties of these polyamideimides were compared to those of the polyimide of benzophenonetetracarboxylic polyamideimide dianhydride/3,3'-diaminobenzophenone (LARC-TPI) because their structures are similar except for the presence of the more flexible amide linkages. These polymers exhibited high inherent viscosities and glass transition temperatures. They were made into tough, flexible films which showed good thermal stability and good resistance to organic solvents. Mechanical properties of the PAI films were better than those of LARC-TPI. Films of the 4,4'-isomer polyamide-imide exhibited an exceptionally high modulus and toughness during impact evaluation. (Author abstract) 9 refs.

**081733 POLIURETANOIMIDY Z DIIZOCYJANIANU TOLILENU. I. WŁASCIWOSCI MECHANICZNE I STABILNOSC TERMICZNA.** [Polyurethaneimides from Toluene Diisocyanate. Part I. The Mechanical Properties and Thermal Stability]. The mechanical and thermal properties of polyurethaneimides (PUI) prepared from pyromellitic dianhydride, toluene diisocyanate (TDI) and polyesterdiol of the type of poly(ethylene adipate) have been presented. These properties have been compared with those of PUI from 4,4'-diphenylmethane diisocyanate and of other polymers containing thermostable groupings of aromatic imide and advantages of TDI-PUI have been stated. The influence of concentration of time of storage of PUI solutions on their viscosity has been determined. The IR analysis has been applied in the determination of the progress of thermal imidization reaction. (Author abstract) In Polish. 24 refs.

Masiulanis, Bogumila (Politechnika Gdanska, Pol). *Polimery* v 32 n 10 Oct 1987 p 401-405.

**081734 EFFECT OF MOLECULAR WEIGHT ON THE MECHANICAL PROPERTIES OF POLYAMIDEIMIDE.** Aromatic polyamideimide (PAI) was prepared by the polycondensation of trimellitic anhydride with 4,4'-diphenylmethane diisocyanate. The PAI was fractionated by fractional precipitation. The effect of molecular weight on the tensile strength and elongation of PAI was investigated. The relationship between tensile strength or elongation of fractionated PAI and the degree of polymerization is presented. The tensile strength of a mixture of fractionated PAI with a different molecular weight was found to be given by the sum of the product of mass fraction and tensile strength of their fractions. (Edited author abstract) 10 refs. In Japanese.

**081735 CHAIN CONFORMATION AND STIFFNESS OF AROMATIC POLYIMIDES CONTAINING ONE FLEXIBLE JOINT IN THE DIANHYDRIDE CONSTITUENT.** Highly oriented fibres made of aromatic polyimides prepared from aromatic diamines and dianhydrides of tetracarboxylic acids containing one flexible joint between benzene rings were investigated by X-ray diffraction combined with elastic deformation directly in the diffractometer. A single method based on the relationships derived by T. Miyazawa was employed to determine chain conformations and compliance of chains in the crystal lattice. The calculated compliance parameters agree well with values determined experimentally from the modulus of elasticity of crystal lattice deformed along the direction of polymer chains. Parameters characterizing deformation of internal rotation angles have been estimated. (Edited author abstract) 15 refs.

## Metallizing

**081736 ROLE OF COLLOID FORMATION, IMIDIZATION, AND AGGREGATION IN THE STRUCTURE OF BTDA-ODA POLYIMIDE FILMS MODIFIED WITH GOLD.** High-temperature polyimide films with metallic gold surfaces can be fabricated by the incorporation of a soluble metal salt into a solution of polyamic acid. Thermal treatment of these solutions produces the polyimide, decomposes the metal salt to metallic gold, and promotes the formation and growth of the metallized surface. What appeared to be a continuous metallic surface was actually composed of large gold aggregates. It is suspected that the formation of colloidal gold during the initial thermal treatment provides precursors to the large metal aggregates. Thermal treatment has been shown to influence the size and distribution of the aggregates. The shape of the aggregates suggests that diffusion-limited aggregation may be responsible for the unique shape of some of the gold aggregates. (Author abstract) 13 Refs.

## Optical Properties

**081737 PYROLYSATION KINETICS AND OPTICAL PROPERTIES OF POLYIMIDE FOIL.** This paper is devoted to the pyrolysis kinetics of polyimides as evidenced by changes in the optical transmittance. The main result is to show that the pyrolysis can be understood as a thermally activated process with an activation energy governed by the optically observed fundamental bandgap of polyimide. The optical measurements are probing the bulk of the foils, and are believed to be adequate for testing the chemical bond breaking in the initial phase of pyrolysis, whereas the electrical and mechanical properties change strongly only when a percolation threshold is exceeded. 12 refs.

## Photosensitivity

**081738 SYNTHESIS AND CHARACTERIZATION OF PHOTOCSENSITIVE POLYIMIDES.** All aromatic polyimides bearing diarylsulfide linkages in the main chain were prepared either by condensation of sulfur containing dianhydride with an aromatic diamine or the condensation of a sulfur containing aromatic diamine with a dianhydride. Phenylation with diphenyl iodonium salts was then used to convert the diarylsulfide groups to triarylsulfonium salts. The resulting photosensitive polyimides were shown to undergo main chain cleavage during

photolysis using UV irradiation. These new polyimides are candidates for positive working, high temperature photoresist materials. (Author abstract) 11 refs.

## Physical Properties

**081739 DAMAGE TOLERANT COMPOSITES.** Recently, researchers at duPont recognized the need for a material with capabilities beyond those of high grade epoxies, in terms of toughness and damage tolerance. The result is a composite material designated Avimid K-III, a new polyimide composition of pyromellitic dianhydride and aromatic diamine. (The diamine was designed to lower the glass transition temperature and retard crystallization.) The composite expands the range of structural shapes that can be fabricated through thermoplastic molding processes.

Spiegelman, Phillip P. (DuPont Inc, USA); Aldrich, Donald C.; Waughtal, Richard F. *Aerosp Eng (Warrendale PA)* v 7 n 12 Dec 1987 p 8-11.

**081740 SUPER TOUGH POLYIMIDE.** SP polyimide material has no observable glass transition temperature or melting point below a decomposition temperature which is in excess of 400°C. Although this behavior is a key feature in performance, because of the resin's intractability, it also represents a major obstacle to the effective fabrication of complex structural parts. Researchers at duPont overcame this problem by using powder metallurgy forming techniques which changed the morphology of the molding resin. The result is Vespel ST, a high temperature polyimide with significantly increased strength and toughness. An already tough Vespel SP was made super tough.

## Processing

**081741 MATERIAL AND PROCESSING TECHNOLOGIES OF POLYIMIDE FOR ADVANCED ELECTRONIC DEVICES.** Advanced material and processing technologies of polyimide applied to various substrates were investigated and studied for high density electronic devices. Precisely controlled temperature profiles in each processing step can realize required chemical structures of polyimide materials and the excellent polyimide films. Thick film patterning of photosensitive polyimide is extremely difficult because the exposed top layer is dissolved before the unexposed area is developed as the result of UV absorption and reaction at the bottom being less than that of the top layer. For removing the thin film residue on copper and/or copper containing alloys, a simple patterning process using a solution containing hydrazine has been developed. Newly developed techniques such as screen printing, shower developing, and microwave-assisted curing enable the realization of more precise patterning of photosensitive polyimide. (Edited author abstract) 8 refs.

**081742 PROCESSING OF PHOTOSENSITIVE POLYIMIDES FOR PACKAGING APPLICATIONS.** Photosensitive polyimides have been investigated as substitutes for a standard aqueous base-etchable polyimide. The application uses a ceramic base module on which two layers of metal circuits are separated by a polyimide dielectric. Using a photosensitive polyimide reduces the number of steps and shortens the process time required to form the via interconnections. Processing properties and

material properties were studied to select a material which would give optimum throughput. The photosensitive polyimides investigated were primarily developed for IC processing; adaption to packaging applications requires adjustment of processes. Polyimide application, drying, baking, exposure, developing, and final cure must be optimized to use these materials successfully. 8 refs.

**Pyrolysis** See Also POLYMERS—Heating.

**081743 STRUCTURAL DETERMINATION OF PYROLYZED PI-2525 POLYIMIDE THIN FILMS.** Polyimide was pyrolyzed in an argon atmosphere at various temperatures, and thermally converted to amorphous carbon films. The irreversible change of polyimide under progressive heat treatment is characterized by three successive structural changes: pyrolysis, carbonization, and graphitization. X-ray photoelectron spectroscopy (XPS) studies show that the polyimide starts to dissociate at pyrolysis temperatures above 500°C. At temperatures higher than 650°C most functional groups of polyimide decompose to evolve gases from the sample. The polyimide then gradually becomes more carbon rich. It is believed that at pyrolysis temperature higher than 650°C the polyimide starts to form heterocyclic structures with residual oxygen and nitrogen incorporated into the heterocyclic carbon rings. (Edited author abstract) 23 refs.

Hu, C.Z. (Univ of Utah, Salt Lake City, UT, USA); Andrade, J.D.; Dryden, P. *J Appl Polym Sci* v 35 n 5 Apr 1988 p 1149-1160.

**081744 SURFACE STRUCTURE OF PYROLYZED POLYIMIDE.** X-ray photoelectron spectroscopy analysis shows that polyimide is thermally converted to glassy carbon during pyrolysis. Scanning tunneling microscopy gives direct evidence of the existence of small graphitic domains in the amorphous carbon matrix, and we believe that those surface graphitic structures may play a major role in the biocompatibility of carbon surfaces. (Author abstract). 15 Refs.

## Radiation Effects

**081745 NEW CONDUCTING AND OPTICAL PROPERTIES INDUCED IN POLYIMIDE BY ION BEAM IRRADIATION.** Ion beam irradiation of polyimide films leads to the formation of new materials exhibiting enhanced electrical conductivity (of the order of  $10^2 \Omega^{-1} \text{cm}^{-1}$ ) and an increase of the optical absorption in the visible. The formation of these carbon-rich products has been studied by the kinetics of hydrogen evolution during irradiation, which can be described by an exponentially decreasing law. The modification of the optical absorption for different wavelengths is in agreement with this variation. These results imply the existence of a saturated stage reached when the overlap between the strongly disordered cylindrical volumes formed around the individual tracks is complete. (Author abstract) 12 refs.

Davenas, J. (Univ Claude Bernard (Lyon I), Villeurbanne, Fr); Xu, X.L.; Boiteux, G. *Synth Met* v 24 n 1-2 Apr 1988, Proc of the Second Fr-Pol Colloq on Low Dimens Org Conduct and Electroactive Polym, Nancy, Fr, May 12-15 1987 p 81-87.

## Spectroscopic Analysis

**081746 REACTIONS AT THE POLYIMIDE-METAL INTERFACE.** Ultra-high-vacuum spectroscopic techniques are utilized to investigate the mechanism of the interfacial reactions of copper and titanium with polyimides. Ultra-violet photoemission spectroscopy of in situ deposited Cu on polyimides suggests that

covalent interaction between the metal and the polymer is absent. Model studies confirm this finding. Alternatively, deposition of Ti onto polyimides shows the presence of strong covalent interaction between the imide moiety of the polymer backbone and the metal. Solution model studies support a mechanism for the Ti-polyimide reaction involving initial Ti-O bond formation followed by Ti-C bonding at higher coverages of material. (Author abstract) 13 refs.

Freilich, S.C. (DuPont, Wilmington, DE, USA); Ohuchi, F.S. *Polymer* v 28 n 11 Oct 1987 p 1908-1914.

**081747 SPECTROSCOPIC STUDY OF THE CHEMICAL CONVERSIONS OF AROMATIC POLYIMIDES CONTAINING DOUBLE AND TRIPLE CARBON-CARBON BONDS.** Infrared spectroscopy and high resolution NMR in a solid body have been used to study the opening of the double and triple bonds contained in the diamine fragments of some aromatic polyimides at 20-400°C. The consumption of the double and triple bonds on heating begins simultaneously and occurs synchronously by more than 80-95%. A small number of triple bonds remains even at 400°C. (Author abstract) 9 refs.

Kol'tsov, A.I. (USSR Acad of Sciences, USSR); Mikhailova, N.V.; Gribanov, A.V.; Koton, M.M.; Zhukova, T.I.; Bobasheva, A.S.; Kheinmaa, A.I.; Lippmaa, E.T. *Polym Sci USSR* v 23 n 12 Dec 1987 p 2800-2804.

**081748 MOLECULAR ORBITAL ANALYSIS OF THE XPS SPECTRUM OF A FLUORINE CONTAINING POLYIMIDE: PMDA-BDAF.** The results of XPS measurements and molecular orbital calculations performed on the fluorine containing polyimide, PMDA-BDAF, are presented. The calculated carbon 1s (C1s) core energy level positions are compared with the level positions inferred from the XPS measurements. Within Koopman's approximation, the observed shape of the main XPS peak is consistent with the calculated distribution of C1s levels under this peak. Comparison of the magnitude of the carbonyl XPS peak intensity with the main peak intensity indicates a carbonyl C1s signal deficiency compared with that expected for 'ideal bulk stoichiometry' i.e., for a polymer with no crosslinks or chain terminations. (Edited author abstract) 17 refs.

**081749 EFFECT OF TEMPERATURE ON THE INFRARED SPECTRA OF A POLYIMIDE.** The effect of high temperature on the infrared spectra of fully cured PMDA/ODA polyimide is discussed. Changes in some bands can be explained by Boltzmann effects on the distribution of excited states. Other bands, in particular the  $1780\text{-cm}^{-1}$  band that is often used for cure measurements, change in ways that cannot be related to Boltzmann's equation. These band position and intensity changes are explained as configurational changes occurring during heating. Determination of correction factors for integrated peak areas from spectra taken at elevated temperature are discussed. (Author abstract) 14 refs.

Snyder, Randy W. (IBM Endicott, NY, USA); Sheen, C. Wade; Painter, Paul C. *Appl Spectrosc* v 42 n 3 Mar-Apr 1988 p 503-508.

**081750 FT-IR METHOD FOR PERFORMING DYNAMIC KINETIC EXPERIMENTS.** A method is shown for the determination of kinetic parameters from dynamic FT-IR experiments. The effect heating rate has on the reproducibility of the calculated activation energy is discussed. The curing of PMDA/ODA polyimide at several heating rates is given as an example. (Author abstract) 10 refs.

Snyder, Randy W. (IBM, Endicott, NY, USA); Sheen, C. Wade. *Appl Spectrosc* v 42 n 4 May-Jun 1988 p 655-658.

**081751 FOURIER TRANSFORM IR REFLECTION TECHNIQUES FOR CHARACTERIZATION OF POLYIMIDE FILMS ON COPPER SUBSTRATES.** In this study, we have used Fourier transform IR spectroscopy to study the copper-catalyzed degradation of polyimide and its precursor, polyamic acid. We have examined the system in both air and nitrogen and with both copper and chromium as test substrates. Also discussed in this paper is the application of two new spectroscopy techniques: surface electromagnetic wave spectroscopy and grazing-angle incident metal overlayer attenuated total reflection spectroscopy. The combined use of all three experimental methods allows us to examine the interfacial regions of the polyimide/copper system fully. (Edited author abstract) 25 refs.

Kelley, Kristen (Case Western Reserve Univ, Cleveland, OH, USA); Ishino, Yuichi; Ishida, Hatsuo. *Thin Solid Films* v 154 n 1-2 Nov 12 1987, Pap Presented at the Int Conf on Metall Coat - Part II, San Diego, CA, USA, Mar 23-27 1987 p 271-279.

## Structure

**081752 CHEMICAL STRUCTURES AND PROPERTIES OF LOW THERMAL EXPANSION COEFFICIENT POLYIMIDES.** The relationships between chemical structures of various aromatic polyimides and their thermal expansion coefficients, were investigated and the properties of low thermal expansion polyimides were elucidated. Such low values were observed for polyimides obtained from pyromellitic dianhydride or 3,3',4,4'-biphenyltetracarboxylic dianhydride and aromatic diamines, which included only benzene or pyridine rings fused at para-positions without a flexible linkage. It was proposed that these low thermal expansion coefficients were related to the linearity of their polymer molecular skeletons. In particular, PIQ-L100 (Hitachi Chemical Co. Ltd) is one such low thermal expansion polyimide and it has excellent mechanical properties, thermal stability, and low absorbed moisture content. (Author abstract) 21 Refs.

Numata, Shunichi (Hitachi Ltd, Hitachi, Jpn); Kinjo, Noriyuki; Makino, Daisuke. *Polym Eng Sci* v 28 n 14 Jul 1988 p 906-911.

**Synthesis** See Also GASES—Permeability, Mechanical.

**081753 PMR POLYIMIDE COMPOSITIONS FOR IMPROVED PERFORMANCE AT 371°C.** Studies were conducted to identify matrix resins which have potential for use at 371°C (700°F). Utilizing PMR methodology, neat resin moldings were prepared with various monomer reactants and screened for thermo-oxidative stability at 371°C (700°F) under both ambient and four atmospheres air pressure. The results of the resin screening studies indicate that high molecular weight (HMW) formulated resins of first (PMR-15) and second (PMR-II) generation PMR materials exhibit lower levels of weight loss at 371°C (700°F) than PMR-15 and PMR II resins. (Author abstract) 2 refs.

**081754 NOVEL BISMALIMIDES VIA EPOXY-CARBOXY ADDITION REACTION: SYNTHESIS CHARACTERIZATION AND THERMAL STABILITY.** The present paper describes the synthesis and characterization of bismaleimides containing epoxy backbone between the maleimide ends. In this synthesis, a preformed maleimide containing carboxylic acid function is reacted with an epoxy resin by melt condensation. The resin products were analyzed by gel permeation chromatography. Infrared and C NMR spectroscopy were used for characterization of these materials. Differential scanning calorimetry and thermogravimetric analysis were used to establish cure characteristics and thermal stability of these materials. 16 refs.

**081755 SYNTHESIS AND CHARACTERIZATION OF AROMATIC POLYIMIDE AND POLYAMIDE-IMIDE FROM 2,5-BIS(4-ISOCYANATOPHENYL)-3,4-DIPHENYLTHIOPHENE AND AROMATIC TETRA- AND TRICARBOXYLIC ACIDS.** Soluble polyimide having an inherent viscosity up to 1.4 dL/g was synthesized by the high-temperature solution polycondensation of 2,5-bis(4-isocyanatophenyl)-3,4-diphenylthiophene with 3,3',4,4'-benzophenonetetracarboxylic dianhydride. The polycondensation of the tetraphenylthiophene diisocyanate with trimellitic anhydride afforded polyamide-imide with an inherent viscosity up to 0.9 dL/g. These polymers showed limited solubility in organic solvents and had glass transition temperatures around 320°C. (Author abstract) 9 refs.

**081756 POLYIMIDES FROM 2,5-BIS(p-AMINOPHENYL)PYRIMIDINE AND AROMATIC DIANHYDRIDES.** The synthesis and properties of polyimides obtained by the polycondensation of 2,5-bis(p-aminophenyl)pyrimidine with a variety of aromatic dianhydrides has been examined. The linear structure of this diamine, which is a heterocyclic analog of terphenyl, enables films to be obtained which possess high mechanical strength and thermal stability. It is shown that the deformation-strength properties of polyimide films are highly dependent on the proportion of isoimide units in the prepolymer, before thermal treatment. Lower proportions of isoimide units correspond to higher physicochemical characteristics. For example, in the case of the polyimide obtained by thermal treatment of the prepolymer containing 23% of the isoimide units, the strength at rupture is 200 MPa, and extension at rupture is 12%. The polyimide obtained from the prepolymer containing 7% of isoimide units has a strength of 220 MPa and extension 25%. 7 refs.

**081757 SYNTHESIS AND CHARACTERIZATION OF POLYIMIDES CONTAINING HETEROCYCLIC UNITS.** Five new polyimides containing phenoxaphosphine as well as dibenzothiophene, phenoxathiin, and thianthrene units have been synthesized from 10-phenylphenoxaphosphine-2,3,7,8-tetracarboxylic dianhydride-10-oxide and heterocyclic diamines by the cyclopolycondensation method. These polyimides had inherent viscosities in the 0.75-1.10 dL/g range in conc. H<sub>2</sub>SO<sub>4</sub> at 30°C. All the polymers were characterized by elemental analysis, density, solubility, crystallinity, IR spectra, and thermal methods. (Author abstract) 12 refs.

**081759 HIGH TENACITY AND HIGH MODULUS FIBERS FROM WHOLLY AROMATIC POLYESTERIMIDES.** Wholly aromatic polyesterimide fibers were prepared from rigid aromatic diamines and 4,4'-(arylene-dioxydicarbonyl)diphthalic anhydride by wet-spinning the N-methylpyrrolidone solutions of their precursor poly(amic acids) and then imidizing the fibers chemically. In general, higher crystalline polymers gave fibers having higher initial modulus (Mi), but lower tenacity (T) than lower crystalline polymers. For example, the fiber from p-phenylenediamine and 4,4'-(p-phenylenedioxydicarbonyl)diphthalic anhydride (TmHTm) showed T of 12.6 g/d and Mi of 1420 g/d. Random copolymers composed of a rigid diamine, TmHTm and pyromellitic dianhydride (PMDA) were also spun, and 2-chloro-p-phenylenediamine-TmHTm-PMDA (100 : 60 : 40) copolymer yielded a fiber with T of 20.9 g/d and Mi of 1350 g/d. **081761 SYNTHESIS AND CHARACTERIZATION OF BTDA-BASED POLYAMIDE-IMIDES.** A series of thermally-stable, tough, linear polyimides containing amide linkages were prepared. These materials have potential as high temperature films and coatings as well as matrix resins in graphite reinforced structures. The new polyamide-imides were prepared by reacting a group of isomers of dianaminobenzanilide (DABA) with 3,3',4,4'-benzophenonetetracarboxylic dianhydride (BTDA) to form the polyamide-acid with subsequent thermal conversion to the polyamide-imide (PAI). They were made into tough, flexible films which showed good thermal stability and good resistance to organic solvents. Mechanical properties of the PAI films were better than those of LARC-TPI. **081762 PROCEEDINGS OF SECOND INTERNATIONAL CONFERENCE ON POLYIMIDES: SYNTHESIS, CHARACTERIZATION AND APPLICATION.** This conference proceedings contains 53 papers, eight of which are in abstract form only. The main topics of the conference are polyimide synthesis, its characterization and its application. Methods of surface modification for enhanced surface reactivity, which provides new functionalities, are described. Preparation of polyimides for specific electronic applications are reported. The characterization of new polyimides, such as new photosensitive polyimide device-grade polyimide etc; is discussed. Synthesis of copolyimides with different groups are also discussed. Technical and professional papers from this conference are

indexed and abstracted with the conference code no. 10207 in the Ei Engineering Meeting (TM) database produced by Engineering Information, Inc.

## Synthetics

**081763 SYNTHESIS AND CHARACTERIZATION OF O-NITROSUBSTITUTED POLYIMIDES.** Poly(o-nitro)imides have been synthesized by one-stage polycondensation in DMAc at 130°C of 1,3-dichloro-4,6-dinitrobenzene with the di-potassium salt of pyromellitic or 3,3',4,4'-benzophenonetetracarboxylic acid dimide. The structure was confirmed by elemental analysis, IR, and UV-Vis spectroscopy, and the influence of the o-nitrosobstituents on the solubility and the thermal stability of the prepared polymers was studied. These polymers could be used as pyrone precursors. The model compound for these polymers has been also prepared by condensation of 1,3-dichloro-4,6-dinitrobenzene with potassium phthalimide. (Author abstract) 21 refs.

## Thermal Expansion

**081764 RE-EXAMINATION OF THE RELATIONSHIP BETWEEN PACKING COEFFICIENT AND THERMAL EXPANSION COEFFICIENT FOR AROMATIC POLYIMIDES.** The existence of a possible relationship between molecular packing coefficient and thermal expansion coefficient for various aromatic polyimides was investigated. Rod-like low-thermal-expansion polyimides without side groups were seen to have very high packing coefficients, pointing to free volume as a factor in lowering their thermal expansion coefficients. But the small packing coefficients for low-thermal-expansion polyimides with side groups indicated that this was not so. Also, even if the large packing coefficients tended to increase the Young's moduli for these polyimides without side groups, the rod-like polyimides with side groups have small packing coefficients and large Young's moduli. The polyimides with low packing coefficients were found to have very small diffusion coefficients for water vapor. (Author abstract) 24 refs.

**081765 POLYIMIDE FILM PROPERTIES AND SELECTIVE LPCVD OF TUNGSTEN ON POLYIMIDE.** du Pont PI-2575-D polyimide films were characterized to determine their suitability for use as an interlevel dielectric with a selective tungsten via fill process. Polyimide films cured at 400° and 440°C were found to breakdown at voltages greater than  $1 \times 10^6$  V/cm. The pinhole density, when processed in a non-cleanroom environment, is below  $1 \text{ per cm}^2$ . The dielectric constant for 1.6  $\mu\text{m}$  films is 3.9. Adhesion to thermal oxide is 100% for films in boiling water up to 1h. The maximum moisture absorption is 1.7 w/o at 90% relative humidity. Perfect tungsten selectively was achieved in the absence of nearby tungsten surfaces at 216°C, 0.75-7.5 torr total pressure, 15:1 H<sub>2</sub>:WF<sub>6</sub> and times to 210 min. (Edited author abstract) 22 refs.

**081766 CHEMICAL ASPECTS OF REACTIVE METAL AND ENERGETIC ION INTERACTIONS**

**ON POLYIMIDE.** [X-ray photoemission and in situ oxygen uptake studies have been performed on polyimide surfaces exposed to controlled ion etching, reactive metallization, or the two acting in concert. Although the ion etching process utilized in the current study was highly destructive in terms of bond scission and was found to exhibit enhanced selectivity for the removal of carbonyl oxygen atoms, the resulting surface was not observed to be reactive to a subsequent in situ oxygen exposure. This observation suggests that the bond cleavage induced by energetic ions does not produce a surface containing significant densities of stable organic radicals but, rather, results in the extensive cross-linking of the surface with the concomitant formation of highly unsaturated or graphitelike residues. Exposure of an unspattered polyimide surface to Al deposited under UHV conditions results in the reduction of surface carbonyl functional groups. (Edited author abstract)] 15 refs.

**081767 XPS STUDY OF THE COMPOSITION OF THIN POLYIMIDE FILMS FORMED BY VAPOR DEPOSITION.** Films of polyimide (<8 nm) were formed on a polycrystalline silver surface following heating of a vapor-deposited layer of 4,4'-oxydianiline (ODA) and 1,2,4,5-benzenetetracarboxylic anhydride (PMDA). The imidization reaction leading to polymer formation was followed in situ with X-ray photoelectron spectroscopy. The uncertainties inherent in a quantitative analysis of the composition of the top 8 nm of the surface layer (corresponding to the sampling depth of the technique) are discussed with respect to thick films of ODA and PMDA adsorbed on a clean Cu(111) surface at 200 K. The fully cured polyimide film contains excess ODA-like and PMDA-like constituents as trapped molecules or terminal groups. (Author abstract) 15 refs.

## Transport Properties

**081768 SORPTION AND DIFFUSION OF CARBON DIOXIDE IN POLYIMIDE FILMS.** The sorption isotherms of carbon dioxide in a polyimide film sample were measured by a pressure decay method at 30, 40, 50, and 60°C and pressures up to 1.7 MPa. The mean permeability coefficients at the same temperatures were measured by a variable volume method at applied upstream pressures up to 3 MPa. The sorption equilibria at these temperatures were found to be well described in terms of a dual-mode sorption model. The pressure dependence of the mean permeability coefficients at these four levels of temperatures did not satisfactorily follow a dual-mode mobility model, but could be well simulated by a modified mobility model. (Edited author abstract) 9 refs.

## POLYISOPRENE

### Aging

**081769 KINETICS AND MECHANISM OF STRESS RELAXATION OF POLYISOPRENE VULCANIZATES UNDER OZONE AGING.** The paper deals with the kinetics of the decrease in stress ( $\Delta_p$ ) in polyisoprene vulcanizates at 22°C and in an ozone concentration of  $(1.8-7.3) \times 10^{-8} \text{ mol litre}^{-1}$  and the kinetics of degradation of polyisoprene macromolecules in solution. It has been found that the number of ruptured macromolecules increases linearly with time, whereas the time dependence of  $\Delta_p$  is more complex. A mechanism has been proposed, which links the stress relaxation with the chemical processes which occur during the action of ozone on vulcanizates. It has been shown that  $\Delta_p$  involves two

components possessing a common chemical nature, but different localization; namely, weakening of the sample by growing cracks and chain degradation on the surface of uncracked sites on the sample. (Edited author abstract) 14 refs.

### Degradation

**081770 SIMULATION OF MOLECULAR WEIGHT DISTRIBUTION AFTER POLYMER BREAKDOWN. II. DEGRADATION OF cis-POLYISOPRENE BY ULTRASOUND AND OZONOLYSIS.** cis-Polyisoprene was degraded by two different methods, ultrasound and ozonolysis. Monte Carlo simulation of the molecular weight distribution after breakdown gave very poor fits to the observed data when the extent of degradation was estimated from number-average molecular weight data. Much improved fits were obtained when the degradation index was estimated by a least-squares method. (Author abstract) 15 refs.

### Melting

**081771 ASSOCIATION BEHAVIOR OF END-FUNCTIONALIZED POLYMERS. 2. MELT RHEOLOGY OF POLYISOPRENES WITH CARBOXYLATE, AMINE, AND ZWITTERION END GROUPS.** Viscoelastic behavior in the melt state was investigated for polyisoprenes with associating groups on the ends of the chain and compared with the behavior of their nonfunctionalized counterparts. Narrow distribution samples were prepared with a range of molecular weights by anionic polymerization; functional groups such as tertiary amine, zwitterion, carboxylic acid, and sodium carboxylate were introduced through the initiator as well as by appropriate postpolymerization reactions. Melt viscosities of the monofunctional samples were examined for evidence of end group clustering. (Edited author abstract) 64 refs.

### Morphology

**081772 MORPHOLOGY OF SOLUTION CRYSTALLIZED TRANS-1,4-POLYISOPRENE.** The film formation method has been successfully used to grow single crystals and other complex morphological features of low melting form (LMF) and high melting form (HMF) of trans-1,4-polyisoprene (TPIP). Below 40°C dilute amyl acetate solution gave hexagonal shaped LMF crystals. Thick and elongated hexagonal shaped morphology was shown by HMF crystals at temperatures above 40°C. Straight faces and sharp corners of the single crystals, and also of complex crystals, acquired round shapes when highly polydispersed TPIP was used for crystallization. (Author abstract) 19 refs.

## Oxidation

**081773 INFLUENCE OF MECHANICAL STRESS ON OXIDATIVE-DEGRADATIVE PROCESSES IN POLYISOPRENE.** The oxidation of SKI rubber under the action of mechanical stress has been investigated. The kinetics of oxidation of SKI under conditions where high stress levels alternate with periodic rest results in marked inhibition of the process compared with oxidation under lower stress level. The molecular composition of carbonyl compounds was found to depend on the magnitude of the applied stress. (Author abstract). 20 Refs.

## Radiation Effects

**081774 DEVELOPMENT OF TRANS-1,4-POLYISOPRENE FOR SUTURELESS VASCULAR ANASTOMOSIS.** Radiation crosslinked trans-1,4-polyisoprene (t-PIP) is shown to be effective as a heat shrinkable connector for severed blood vessels. The sutureless vascular anastomosis system (SVAS) requires a plastic sleeve with the following requirements: biocompatibility, heat shrinkability, melting point 50 to 60°C, and proper mechanical properties. The effect of irradiation by cobalt-60 gammas on pertinent physical properties were determined. The results show no change in the gel fraction and mechanical strength. An in-vitro test of the processed t-PIP with intravenous saline solution demonstrates that the material undergoes no physical property changes after five months. Also, biocompatibility of the crosslinked t-PIP sleeve was established by tests. The results of all the tests demonstrated that the procedure and the t-PIP sleeve were effective and safe. (Edited author abstract) 9 refs.

## Solutions

**081775 ASSOCIATION BEHAVIOR IN END-FUNCTIONALIZED POLYMERS. 1. DILUTE SOLUTION PROPERTIES OF POLYISOPRENES WITH AMINE AND ZWITTERION END GROUPS.** The dilute solution properties of linear polyisoprenes with a highly polar sulfo-zwitterion group on one end of the chain were examined in several solvents by osmometry, light scattering, and viscometry. The polymers were prepared by anionic polymerization with initiation by (3-(dimethylamino)propyl)lithium. The terminal tertiary amine groups were converted to zwitterions by treatment with cyclopropane sulfone. A few linear and star materials with all ends functionalized were also prepared. The zwitterion-capped polymers were found to associate strongly in aliphatic hydrocarbons. (Edited author abstract) 58 refs.

Davidson, Neil S. (Exxon Research & Engineering Co, Annandale, NJ, USA); Fettes, Lewis J.; Funk, Walter G.; Graessley, William W.; Hadjichristidis, Nikos. *Macromolecules* v 21 n 1 Jan 1988 p 112-121.

**081776 DIELECTRIC NORMAL MODE PROCESS IN SEMIDILUTE AND CONCENTRATED SOLUTIONS OF cis-POLYISOPRENE.** The dielectric normal mode process was studied for semidilute and concentrated solutions of cis-polyisoprene (cis-PI) dissolved in a good solvent, benzene, and a  $\Theta$  solvent, dioxane. The mean-square end-to-end distance  $\langle r^2 \rangle$  of cis-PI was determined from the dielectric relaxation strength. The relaxation time in solutions of low molecular weight cis-PI (PI-09) with weight-average molecular weight  $M_w$  of  $8.6 \times 10^3$  was converted to the friction coefficient  $\zeta$  per monomeric unit by using the Rouse theory. It is found that the exponent for benzene solutions was slightly higher

than that predicted by the dynamic scaling theory proposed by P.G. de Gennes, while the exponent in dioxane solutions was lower than the theoretical value. The widths of the loss curves for solutions of PI-164 increased with increasing concentration. The factors affecting the breadth of the loss curve are discussed. (Edited author abstract) 40 refs.

Adachi, Keiichiro (Osaka Univ, Toyonaka, Jpn); Kotaka, Tadao. *Macromolecules* v 21 n 1 Jan 1988 p 157-164.

**081777 DILUTE SOLUTION PROPERTIES OF cis-POLYISOPRENE IN CYCLOHEXANE AND 1,4-DIOXANE.** Static light scattering and viscosity measurements were made on five cis-polyisoprene fractions of weight-average molecular weight  $M_w$  ranging from  $0.33 \times 10^6$  to  $7.2 \times 10^6$  in cyclohexane (good solvent) at 25°C and 1,4-dioxane ( $\Theta$  solvent) at 34.7°C. The maximum values for static and dynamic (=Stokes radius,  $R_H$ ) expansion factors  $\alpha_3^3$  and  $\alpha_H^3$  of the highest molecular weight sample were 13 and 8, respectively, and were the largest ones obtained so far for light scattering. With these large values, excluded-volume effects and hydrodynamic interaction on chain segments of highly swollen flexible polymers in dilute solutions were tested through the two-parameter theory. (Edited author abstract) 46 refs.

**081778 NMR RELAXATION CROSSOVER FROM MELTS TO DILUTED SOLUTIONS OF POLYISOPRENE IN THE LIGHT OF THE TUBE CONCEPT.** In a series of previous papers we have developed the three-component concept of chain fluctuations. It takes into account the special structure/dynamics relationship caused by topological restraints such as the tube. The application of this formalism permitted us the description of the frequency, molecular weight and temperature dependences of the NMR relaxation times in polymer melts. In particular, limiting cases characteristic for motions restricted by the tube topology could well be verified. The existence of characteristic molecular weights, for instance, could thus be explained. The purpose of the present paper is to probe experimentally the effect of dilution on the tube restraints. If the increase of the tight-tube diameter can be considered as the predominant consequence of swelling, all fluctuation components determined by the tube properties are expected to be modified by dilution. 10 Refs.

## Spectroscopic Analysis

**081779 SOLID-STATE  $^{13}\text{C}$  NUCLEAR MAGNETIC RESONANCE SPECTRA OF THE  $\alpha$  AND  $\beta$  CONFORMERS OF TRANS-1,4-POLYISOPRENE.** Solid-state  $^{13}\text{C}$  nuclear magnetic resonance (nmr) was used to study the two different conformers of trans natural rubber (NR). The  $\alpha$  and  $\beta$  conformers of trans NR were observed to give different  $^{13}\text{C}$  chemical shifts. The relative magnitude and direction of the chemical shift for the methyl carbon on the  $\beta$  conformer are predicted by a steric perturbation model. The  $\alpha$  conformer gave longer relaxation times than the  $\beta$  conformer. For this highly mobile semicrystalline polymer, spin diffusion was not a major contributor to the relaxation process. (Author abstract) 25 refs.

**081780 INFRARED SPECTRAL CORRELATIONS FOR CRYSTALLINE AND AMORPHOUS TRANS-1,4-POLYISOPRENE.** The infrared spectra for  $\alpha$ - and  $\beta$ -trans-1,4-polyisoprene are compared, and a correlation is found between both the frequencies of their observed vibrational modes and their potential energy distribution from normal coordinate calculations for a single chain. Each band in the  $\beta$  spectrum corresponds to

either one or two bands in the  $\alpha$  spectrum. Correlation between each of the spectra of the two crystalline forms and the amorphous TPI is used to assign the infrared bands of the latter. (Author abstract). 18 Refs.

Gavish, Michal (City Univ of New York, New York, NY, USA); Brennan, Peter; Woodward, Arthur E. *Macromolecules* v 21 n 7 Jul 1988 p 2075-2079.

**081781 FTIR INVESTIGATIONS OF CRYSTALLINITY AND SURFACE REACTION FOR TRANS-1,4-POLYISOPRENE LAMELLAR STRUCTURES CRYSTALLIZED FROM SOLUTION.** Infrared studies of trans-1,4-polyisoprene (TPI) and of block copolymer derivatives were carried out. TPI lamellar structures were reacted in suspension so that their surfaces were modified while their crystalline cores remained unchanged. The reactions used were epoxidation and hydrochlorination of the double bond. The infrared spectra of the modified surface were obtained, and tentative band assignments were made. A procedure was developed to obtain the percent crystallinity of TPI lamellar structures from the infrared spectrum by using measurements of the relative intensity of the 1664-1670  $\text{cm}^{-1}$  band in the crystalline and semicrystalline spectra. Effects of pressure on as-prepared and surface-modified TPI lamellar structures were observed. (Author abstract). 21 Refs.

## Stresses

**081782 STRAIN-INDUCED CRYSTALLIZATION IN CIS- AND TRANS-POLYISOPRENE BLENDS.** Strain-induced crystallization (SIC) is studied in blends of cis-1,4-polyisoprene (Hevea rubber) and synthetic trans-1,4-polyisoprene (t-PI). Uncrosslinked solution blends were uniaxially stretched at room temperature, and the dependence of stress and birefringence on time, elongation, and t-PI content was analyzed. Stress and birefringence follow power-law decays. The rates of relaxation decrease with elongation and t-PI content, and the rates of stress relaxation are higher than the rates of birefringence relaxation for the blends studied. (Edited author abstract) 17 refs.

**081783 QUANTITATIVE INVESTIGATION OF THE AMORPHOUS AND CRYSTALLINE COMPONENTS IN TRANS-1,4-POLYISOPRENE FROM SOLUTION.** Trans-1,4-Polyisoprene structures in the  $\alpha$  and  $\beta$  crystalline forms with various morphologies were prepared by using different crystallization procedures. The effects of molecular weight, crystallization temperature, and annealing treatment on the crystalline stem length and the noncrystalline traverse length were investigated by using epoxidation in suspension followed by carbon-13 solution NMR. Preliminary studies were carried out to determine the optimum conditions for quantitative reaction of the double bonds at the lamellar surfaces. Results were obtained suggesting that for many liquids penetration of partially reacted lamellae can take place from the lateral surfaces. (Edited author abstract) 21 refs.

**081784 CARBON-13 NUCLEAR MAGNETIC RESONANCE OF 3,4-/cis-1,4-POLYISOPRENES PREPARED WITH  $\text{Fe}(\text{acac})_3\text{-Al}(\text{i-Bu})_3$  CATALYST.** 3,4-/cis-1,4-polyisoprenes were prepared with  $\text{Fe}(\text{acac})_3\text{-Al}(\text{i-Bu})_3$  catalyst. These polymers are of interest because of their higher 3,4 content and different degree of

crystallinity. The  $^{13}\text{C}$ -NMR spectra of these polymers were much more complex than those previously reported and were assigned using slightly modified empirical parameters based on Gronski et al. In order to further clarify the assignments, hydrogenation of the polymers was carried out, and the  $^{13}\text{C}$ -NMR spectra of the hydrogenated polymers were partially assigned. Based on these assignments, it was found that the existence of long sequences of vinyl monomer units might be a favorable factor for the formation of partially crystallized polymer. (Edited author abstract) 15 refs.

**081785 EFFECT OF n-BUTYLLITHIUM CONCENTRATION ON THE STEREOREGULARITY OF POLYISOPRENE IN NON-POLAR MEDIA.** Homogeneous polymerization of isoprene is carried out in a bench scale 2L reactor at 30°C using different concentrations of n-butyllithium as an initiator in bulk and n-heptane, cyclohexane, n-hexane, benzene and toluene. The stereoregularity of polyisoprene is determined using  $^1\text{H}$  and  $^{13}\text{C}$  NMR spectroscopy. The percentage of cis-1,4 structure increased with the decrease of initiator concentration at constant monomer concentration. The range of initiator concentration is  $10^{-2}$ – $10^{-6}$  mol/l. The cis-1,4 content is also dependent on the nature of solvent(s). A new explanation of the influence of initiator concentration on the stereoregularity of polyisoprene is discussed. (Edited author abstract). 37 Refs.

**081786 SOME FEATURES OF HETEROPHASE GRAFT POLYMERIZATION ON SYNTHETIC FIBERS FROM THERMOPLASTIC POLYMERS.** A considerable effect of structural-physical properties and molecular dynamics of the polymer as a solid on the process of radical graft polymerization to fibers from thermoplastic polymers which have been spun from the melt has been found. In the case of heterophase graft polymerization of vinyl monomers to polypropylene fiber, it has been shown that orderedness of the polymer structure primarily affects the initiation stage. High kinetic parameters of heterophase graft polymerization in oriented systems from thermoplastic polymers can be realized only at temperatures which exceed the glass point of the polymer matrix. 12 refs.

**081787 HOMO- AND COPOLYMERIZATION OF SOME NORBORNADIENE DIMER MONOMERS.** The exo-exo- and endo-endo norbornadiene dimers were synthesized and homopolymerized using the  $\text{Re}(\text{CO})_5\text{Cl}/\text{EtAlCl}_2$  catalyst system. The exo-exo dimer was copolymerized with norbornene, both as a random polymer and as a diblock. In all cases, the polymers obtained were mainly of the ring-retained, rather than ring-opened type, even though  $\text{Re}(\text{CO})_5\text{Cl}/\text{EtAlCl}_2$  is an olefin metathesis catalyst and the monomers are strained

ring systems. (Author abstract) 6 refs.

**081788 NEW NONHYDROLYZABLE ETHER CROSSLINKING AGENT CONTAINING TWO METHACRYLATE UNITS LINKED THROUGH THE  $\alpha$ -METHYL CARBONS.** A report is made on the use of a diester ether and its diacid analog, produced by the hydrolysis of the ether, as crosslinking agents in vinyl polymerization. It is concluded that the diester ether and the diacid are highly reactive crosslinking agents for vinyl polymers. Their superiority to commercially available bis-acrylate esters lies in the fact that the crosslinks formed consist of carbon and ether linkages, which are less susceptible to hydrolysis than the ester linkages of most currently available crosslinking agents. 4 refs.

**081791 GAS-PHASE POLYMERIZATION: ULTRASLOW CHEMISTRY.** The mechanism of formation of polymer molecules in the gas phase is difficult to study because the involatile polymers tend to condense out of that phase. However, new techniques, involving the use of cloud chambers, have enabled workers to use the nucleation of liquid drops in supersaturated monomer vapors to detect single polymer molecules and therefore to work with so few simultaneously growing polymers that aggregation and condensation are avoided. Chain polymerization in which the chain carriers are either radicals or ions can therefore be studied in the vapor. Furthermore, the ability to work with such small concentrations of growing polymeric radicals, for example, makes it possible to avoid encounters between them that lead to recombination and formation of 'dead' polymers that are incapable of further growth. Many aspects of gas-phase polymerization can be studied including, besides radical and ion chains, especially 'ultraslow' chemistry. (Edited author abstract) 48 refs.

Reiss, Howard (Univ of California, Los Angeles, CA, USA). *Science* v 238 n 4832 Dec 4 1987 p 1368-1373.

**081792 COMPARISON OF MICROWAVE AND LOWER-FREQUENCY DISCHARGES FOR PLASMA POLYMERIZATION.** A plasma sustained by surface waves (SW) has been used to study the

deposition rate R of hydrocarbon and fluorocarbon plasma polymer films as a function of excitation frequency  $f = \omega/2\pi$  in the range 12-400 MHz. The SW technique allows one to vary only f while keeping constant all other parameters known to influence R, for example, power density in the plasma P. A plot of R/P at a total pressure of 200m Torr (27 Pa) displays two plateaus, that at  $f < 30$  MHz being about five times lower than that at  $f \geq 100$  MHz. This is attributed to the fact that electron energy distribution functions differ fundamentally at ratio- and 'microwave' frequencies, for the gas pressure range considered. (Edited author abstract) 16 refs.

**081793 SPECTROELECTROCHEMICAL EVIDENCE FOR AN INTERMEDIATE IN THE ELECTROPOLYMERIZATION OF ANILINE.** Polyaniline, a polymer exhibiting high electronic conductivity, has attracted significant research interest in recent years. However, only a few experiments have dealt with the mechanisms of electropolymerization. Spectroelectrochemical studies of aniline ( $\text{C}_6\text{H}_5\text{NH}_2$ ) oxidation in  $\text{NH}_4\text{F} + 2.3 \text{ HF}$  at 1 V vs.  $\text{Cu}/\text{CuF}_2$  have shown that a short living intermediate is created before the formation of polyaniline. The intermediate is diamagnetic and on the basis of the experiments, we propose that it must be the nitrenium cation ( $\text{C}_6\text{H}_5\text{NH}^+$ ). The mechanism of polyaniline formation is rediscussed in view of the reaction of  $\text{C}_6\text{H}_5\text{NH}^+$  with aniline, which follows a pseudo-first-order kinetics and also results in the formation of a polymer with at least two non-equivalent structures. 14 refs.

**081796 POLYMERIZATION OF OPTICALLY ACTIVE  $\beta$ -SUBSTITUTED  $\beta$ -PROPIOLACTONES. IV.  $\beta$ -1,1-DICHLOROALKYL  $\beta$ -PROPIOLACTONES POLYMERIZED WITH ALUMINUM TRIISOPROPOXIDE.** The polymerization of three optically active  $\beta$ -1,1-dichloroalkyl  $\beta$ -propiolactones has been investigated in toluene, at 55°C, using aluminum triisopropoxide ( $\text{Al}(\text{OiPr})_3$ ) as initiator in a range of monomer/initiator molar ratios smaller than 150.  $\beta$ -1,1-dichloroethyl  $\beta$ -propiolactone polymerizes according to a living mechanism. However, the ability to polymerize decreases with an increase in the length of the alkyl substituent. Each of the lactones investigated reacts with  $\text{Al}(\text{OiPr})_3$  in an initiation step that obeys a coordination-insertion mechanism. However, the size of the chloroalkyl substituent

ent has a critical effect on the propagation: when the alkyl group contains more than two methylene units, the insertion of a second monomer becomes exceedingly slow. (Edited author abstract) 28 refs.

**081800 INFLUENCE OF AGITATION ON THE CREATION OF COAGULUM DURING THE EMULSION POLYMERIZATION OF THE SYSTEM STYRENE-BUTYLACRYLATE-ACRYLIC ACID.** This paper gives the results of the estimated coagulum content in the final sample of a dispersion based on styrene-butylacrylate-acrylic acid, prepared by semicontinuous emulsion polymerization. The dependence of the amount of coagulum on the agitation intensity was studied. It was found that it is necessary to divide the results into two regions: (a) for specific power input smaller than 80 W/m<sup>3</sup>; (b) for specific power input greater than 80 W/m<sup>3</sup>. It was found that polymerization scaling up from the point of constant coagulum content in the system studied is possible under the conditions of constant specific power input. For the existence of two regions we propose the following hypothesis according to which increasing mixing intensity improves the temperature and concentration nonuniformity which results in the decrease of coagulum content. From the certain value of specific power input, which is specific for each system, the amount of coagulum starts to increase due to increasing shear stress. (Edited author abstract) 12 refs.

**081802 PHOTOREACTION OF AMPHIPHILIC DIOLEFINS IN MONOLAYERS FORMED ON AN AIR-WATER INTERFACE.** Polymerization in the monolayer or multilayer films has received a considerable amount of attention as one of the methods of controlling molecular arrangement and accordingly, of controlling chemical reactions. We have studied four-center type photopolymerization of diolefinic compounds, which is controlled by the molecular arrangement in the crystal. In order to investigate this reaction in monolayer or multilayer systems, amphiphilic diolefins, i.e., long-chain mono-alkyl esters of p-phenyl-enediacrylic acid (p-PDA), were prepared. Among the p-PDA monoesters prepared, p-PDA mono-n-dodecyl ester (p-PDAmC<sub>12</sub>) and p-PDA mono-n-tetradecyl ester (p-PDAmC<sub>14</sub>) 4) were found to form stable monolayers on aqueous CdCl<sub>2</sub> solution. In this paper, we report on the photoreaction of these monolayers formed on air-water interface and its reaction mechanism suggested by the remarkable increase in surface pressure during irradiation. 12 refs.

**081803 MINIMUM END-TIME POLICIES FOR BATCHWISE RADICAL CHAIN POLYMERIZATION. VIII. PIECEWISE TEMPERATURE POLICY.** The method of the Lagrangian multiplier was applied to minimizing the total reaction time for the general model of radical chain polymerization in the presence of a chain-transfer agent by considering initial initiator concentration and piecewise constant temperature as control variables. Development of this discrete policy makes finding the continuous optimal temperature path for solution polymerization in the presence of a chain-transfer agent possible. The calculation results show that the initial initiator concentration should be kept at the lowest possible value (by which the reaction is strongly dead-ended) and the reaction temperature rises from its lowest in Stage 1 to its highest in the final stage. The reaction time interval decreases from stage to stage. The greater the number of time intervals, the shorter is the total reaction time. Experimental verification of styrene solution polymerizations in the presence and absence of chain-transfer agent shows that the present method is applicable. (Edited author abstract) 12 refs.

**081804 EMULSION POLYMERIZATION: ON THE CHARACTERIZATION OF THE PARTICLE SIZE DISTRIBUTION.** In emulsion polymerization, the polymer particles generated exhibit a size distribution. Broadness of the distribution is usually characterized by the uniformity ( $D_p$ ), a ratio of weight to number average particle sizes, and is found to decrease with reaction time despite the fact that the particle volume distribution is usually broadened. Based on the mathematical model proposed by G. Lichti, R.G. Gilbert, and D.H. Napper, detailed analysis using the method of moment shows that standard deviation of the particle volume distribution

increases with time, while that of the particle diameter distribution decreases with time.  $D_p$ 's of both volume and diameter distributions all show a decrease with reaction time. These results are in agreement with those found experimentally. (Edited author abstract) 22 refs.

**081807 PHOTOINITIATION REACTION OF WATER-SOLUBLE MONOMER WITH BENZOIN ETHYL ETHER INCLUDED IN CYCLODEXTRIN.** Presently, water-soluble photoreagents are preferred for immobilization of enzymes in biosensors. Because conventional oil-soluble photoinitiators were dispersed in such hydrophilic photoreagents, they were unstable and their polymerization rate was small. Proposed here is a new water-soluble photoinitiator that is composed of benzoine ethyl ether (BEE) and cyclodextrin (CD). In one case the organic substance is made stable by inclusion in CD, but in the other case it is made unstable by inclusion in CD. It may be considered that the organic substance is made stable when electron delocalizes with inclusion in CD, but it is made unstable in the opposite case. Asymmetric inclusion polymerization of (z)-2-methyl-1,3-pentadiene with deoxycoale acid is one example of inclusion polymerization, but BEE included in CD differs from it in the respect that CD only supports BEE. The author investigated the stability of BEE included in CD and the polymerization reaction of bifunctional monomer initiated with BEE included in CD. (Edited author abstract) 7 refs.

**081811 KINETIC TREATMENT OF IRREVERSIBLE CYCLOOLIGOMERIZATION OF BIFUNCTIONAL CHAINS AND ITS RELEVANCE TO THE SYNTHESIS OF MANY-MEMBERED RINGS.** The reaction of a bifunctional reactant A-B under batchwise conditions to give macrocycles has been simulated by numerical integration of the proper system of differential rate equations. This was set up considering all the possible processes of concurrent cyclization and polymerization up to a polymerization degree of 12. In order to obtain meaningful yield data for the cyclooligomers, realistic sets of effective molarities (EM) have been considered. The results show how the yields of the various cyclooligomers vary as a function of the initial monomer concentration and provide useful guidelines to achieve maximum selectivity in the synthesis of a given ring. It is clearly shown that the yield of any cyclooligomer is a function of the whole set of EM values. (Edited author abstract) 19 refs.

**081813 EFFECT OF SEED ON POLYMER PARTICLE SIZE AND SIZE DISTRIBUTION IN SEED EMULSION POLYMERIZATION OF VINYL CHLORIDE.** In the emulsion polymerization process whether the problem about the average seed size, the size distribution and the seed amount used will exert any action on the average size as well as size distribution of the final polymer particles formed has been studied. Considering from the concept in respect to desorption and resorption of the free radicals from the polymers in vinyl chloride emulsification polymerization process, it is believed that the major controlling factor on the particle size and its distribution depends most likely upon the magnitude of the total external surface of the seed particles. Experimental results show that either the increase of the average seed size or the decrease of the quantity of the seed used gives no sensible increase of the particle size of the polymer particle formed. Hence, in order to have an appropriate particle size as well as the desired size distribution, seed quantity used should not be decreased and, in general, it should take the amount about 3-5 PERCENT of the total amount of the monomer used by weight. (Author abstract). 8 Refs. In Chinese.

**081814 BENZOCYCLOBUTENE IN POLYMER SYNTHESIS. II. SOLID STATE DIELS-ALDER POLYMERIZATION UTILIZING AN IN SITU GENERATED DIENE AND AN ALKYNE.** A novel class of aromatic imide AB-monomers with benzocyclobutene and an alkyne (primarily phenylethynyl group) as the reactive units have been prepared. The monomers have been utilized in thermally induced Diels-Alder polymerizations. The differential scanning calorimetric study of the AB-monomers provided two observations: (i) primary acetylene began its homopolymerization (202°C max.) before the electrolytic ring opening of benzocyclobutene (270°C max.); (ii) the phenoxy group connecting between phenylacetylenyl group and the aromatic imide fragment suppressed polymerization in Diels-Alder fashion. Furthermore, thermoxidative stability evaluation on the cured samples (250°C for 8 h and then 350°C for another 8 h under N<sub>2</sub> atmosphere), carried out at 650°F (air) for 200 h, indicated the more rigid phenylethynyl phthalimide system was the most heat-resistant. (Author abstract) 15 refs.

**081815 MODEL FOR X-RAY-INDUCED SOLID-STATE POLYMERIZATION.** The solid-state polymerization of disubstituted 1,3-diacetylenes proceeds via a 1,4 addition reaction yielding extended conjugated polymer chains possessing three-dimensional long range order. The reaction can be initiated by thermal annealing, by ultraviolet, visible, e-beam, x-ray, or  $\gamma$ -ray irradiation, or by mechanical stress. Upon initiation, the polymerization reaction proceeds exothermically. A model for x-ray-induced solid-state polymerization based on experimental results obtained with the disubstituted diacetylene, 10,12-pentacosadiynoic acid, is presented. 21 refs.

**081816 SYNTHESIS AND CHARACTERIZATION OF IN SITU ANIONICALLY POLYMERIZED p-AMINOBENZOYLCAPOROLACTAM USING DI- AND TRI-FUNCTIONAL INITIATOR SYSTEMS.** p-Aminobenzoylcaprolactam has been polymerized anionically in a two-step process to produce amide-amide copolymers. Both drawn fibers and unoriented films may be produced using this method. The samples were characterized using FTIR, solution NMR, thermal analysis, viscosity, and mechanical testing. FTIR and NMR revealed the incorporation of both the aramid and amide linkages into the polymer backbone. TGA results gave a lower decomposition temperature than that of both aramid and nylon 6 materials. Intrinsic viscosities averaged 0.5 dL/g for the drawn copolymer samples polymerized by the di-functional initiator. Light microscopy displayed crystalline domains that did not appear to melt even up to 300°C. Mechanical testing showed that the initial moduli of drawn fiber samples to be in the range of 30-80 MPa, while homopolymers of nylon 6 and p-benzamide possessed values of 25 MPa and 2.70  $\times 10^3$  MPa, respectively. (Author abstract) 8 refs.

**081817 STUDIES ON SOME RADICAL TRANSFER REACTIONS BY ENTRAPPING THE RADICALS AS POLYMER ENDGROUPS. III. REACTION OF OH RADICAL WITH HALIDE IONS.** The reactions of OH radical with  $Cl^-$ ,  $Br^-$ ,  $I^-$ , and  $F^-$  ions have been studied by entrapping the product radicals as polymer endgroups which have been detected and estimated by the sensitive dye partition technique. The rate constants of the reactions with  $Br^-$ ,  $Cl^-$ , and  $F^-$  ions have been determined to be  $1.51 \times 10^9$ ,  $1.32 \times 10$  and  $0.92 \times 10^9$  L mol<sup>-1</sup> s<sup>-1</sup>, respectively at 25°C and pH 1.00. Oxidation of  $I^-$  ions liberates  $I_2$  which inhibits the polymerization and the reaction could not be followed by polymer endgroup analysis. The observed order of reactivity  $Br^- > Cl^- > F^-$  is in accordance with the electron affinities of the halide ions. The acidity of the reaction medium has a strong influence on the rate of reaction. (Edited author abstract) 20 refs.

## Calculations

**081818 CONSISTENT VALUES OF RATE PARAMETERS IN FREE RADICAL POLYMERIZATION SYSTEMS.** Inspection of tabulated rate coefficients shows that there is a wide divergence in literature values of kinetic parameters for free radical polymerizations under ostensibly the same conditions. This communication is an attempt to initiate a solution to this problem by seeing if agreement exists on the values of some fundamental kinetic parameters for simple monomers, determined using quite different experimental techniques (e.g., comparing bulk versus emulsion data, 'classical' rate studies versus ESR studies, etc.) 17 Refs.

**081820 MAGNESIUM CHLORIDE SUPPORTED HIGH-MILEAGE CATALYSTS FOR OLEFIN POLYMERIZATIONS. XVIII. EFFECT OF HYDROGEN AND LEWIS BASES.** Hydrogen has been found earlier to increase the initial rate of polymerization by  $\text{MgCl}_2/\text{EB}/\text{PC}/\text{AlEt}_3/\text{TiCl}_4\text{-AlEt}_3/\text{MPT}$ , CW-catalyst ( $+\text{B}_1$ ,  $+\text{B}_2$ ) (EB, ethyl benzoate; PC, p-cresol; MPT, methyl-p-toluate), but decays more rapidly as compared to polymerizations in the absence of  $\text{H}_2$ . In this study the effect of  $\text{H}_2$  was studied when either the internal Lewis base, EB  $\text{B}_1$ , or the external Lewis base, MPT  $\text{B}_2$ , or both are deleted from the CW-catalyst.  $\text{H}_2$  does not affect the stereospecificity of all the catalysts, but causes a slight increase of polymer yield, whereas the yield is virtually unchanged by  $\text{H}_2$  for the catalysts activated with  $\text{B}_2$ . (Edited author abstract) 14 refs.

**081821 MODIFICATION OF OLEFIN POLYMERIZATION CATALYSTS. I. MECHANISM OF THE INTERACTION BETWEEN  $\text{AlEt}_3$  AND Silyl ETHERS.** The interaction between  $\text{AlEt}_3$  and silyl ethers,  $\text{Ph}_n\text{Si}(\text{OMe})_{4-n}$  ( $n=0-3$ ), was followed by  $^{13}\text{C}$ - and  $^{29}\text{Si}$ -NMR techniques in conditions close to those typical for an olefin polymerization reaction with supported Ziegler-Natta catalysts ( $\text{AlEt}_3$ :silyl ether ratios from 1 to 10, temperature range 25-75°C).  $\text{AlEt}_3$  and silyl ethers form instantaneously at ambient temperature a donor-acceptor complex, which is stable at 1:1 molar ratio. In the presence of excess  $\text{AlEt}_3$  the complex decomposes via a mechanism consisting, in the case of  $\text{PhSi}(\text{OMe})_3$ , of five consecutive steps. The decomposition was not inhibited by the presence of 1-hexene. (Edited author abstract) 15 refs.

**081822 HIGHLY ACTIVE SUPPORTED CATALYSTS FOR OLEFIN POLYMERIZATION: PREPARATION AND CHARACTERIZATION OF THE CATALYST.** With use of the support prepared by the reaction of a Grignard reagent with reaction mixture of  $\text{AlCl}_3$  and  $\text{CH}_3\text{Si}(\text{OC}_2\text{H}_5)_3$ , an immobilized active stereospecific titanium catalyst was prepared by the three-step treatment of the support, first with  $\text{TiCl}_4$ , second with ethylbenzoate, and third with  $\text{TiCl}_4$  again. The catalyst was also prepared by the two-step treatment of the support, with the mixture of  $\text{TiCl}_4$  and ethylbenzoate, and with  $\text{TiCl}_4$ . The experimental data support the idea that both  $\text{TiCl}_4$  and ethylbenzoate as donors are immobilized on the surface of the active stereospecific catalyst without any interaction between them. (Edited author abstract) 19 refs.

**081823 OLIGOMERIZATION OF ALKYNES BY HAFNOCENE DICHLORIDE/ETHYLLALUMINUM DICHLORIDE.** The  $\text{Cp}_2\text{HfCl}_2/\text{C}_2\text{H}_5\text{AlCl}_2$  system ( $\text{Cp}=\eta^5\text{-cyclopentadienyl}$ ) was found to be an active homogeneous catalyst for the oligomerization of both terminal and internal alkynes. Apparently, the mechanism of oligomerization occurs by successive insertion of the alkene into the hafnium-carbon bond of a cationic intermediate, as evidenced by the interception of the highly substituted, sterically bulky, 1-trimethyl-silyl-1-propyne. (Author abstract) 11 refs.

**081824 IR STUDY OF THE POLYMERIZATION MECHANISM OF THE PHILLIPS CATALYST.** The IR investigation of the catalytic center of the chromium-(II) surface compound on silica gel (the active center of the Phillips catalyst) showed a broad band at  $2750\text{ cm}^{-1}$ , assigned to the stretching vibrations, and a new IR band at  $1448\text{ cm}^{-1}$ , assigned to the deformation vibration of a methylene group at the chromium(II) surface ion. The known alkylchromium dichloride complexes ( $\text{Cl}_2\text{CrR}(\text{THF})_3$ ), which are the best models at the moment for the Phillips catalyst, show C-H vibrations from the alkyl group between  $2790$  and  $2800\text{ cm}^{-1}$ . (Edited author abstract) 18 refs.

**081825 MIXED ORGANO/OXIDE CHROMIUM POLYMERIZATION CATALYSTS.** Supported chromium oxide catalysts are activated by calcination in dry air at  $400-900^\circ\text{C}$ , which dehydrates the carrier and binds chromium(VI) to the surface. A reduction by ethylene then provides the active species. Alternatively, the carrier can be calcined alone and afterward impregnated with an organochromium compound. Both procedures can produce an active catalyst for ethylene polymerization, but the two types differ considerably in their behavior. A third type is made by reacting an organo-chromium compound with the activated chromium oxide catalyst. (Edited author abstract) 29 refs.

**081826 ISOTACHOPHORESIS FOR THE MICRODETERMINATION OF POTASSIUM PERSULPHATE AS INITIATOR IN EMULSION POLYMERIZATION.** Isotachophoresis (IP) was applied to determine the decomposition rate of potassium persulphate (KPS) as initiator in emulsion polymerization, in comparison with conventional iodometry and ferrometry. For the exact determination, the latter methods needed several milliliters of the emulsion pipetted from the polymerization system, whereas IP did only a few microliters. Moreover, the amount of sulphuric acid produced as the decomposition by-product was simultaneously determined by IP, which is impossible for iodometry and ferrometry. (Author abstract) 13 refs.

**081828 SELECTIVE VINYL CATIONIC POLYMERIZATION OF MONOMERS WITH TWO CATIONICALLY POLYMERIZABLE GROUPS. II. P-VINYLPHENYL GLYCIDYL ETHER: AN EPOXY-FUNCTIONALIZED STYRENE.** p-Vinylphenyl glycidyl ether (VPGE), a styrene derivative with an epoxy pendant, was polymerized by various cationic initiators, and its selective vinyl polymerization was investigated at low temperatures below  $-15^\circ\text{C}$ .  $\text{BF}_3\text{OEt}_2$  (a metal halide) and  $\text{CF}_3\text{SO}_3\text{H}$  (a strong protonic acid) polymerized both vinyl and epoxy groups of VPGE, and produced cross-linked insoluble polymers. The  $\text{HI}/\text{I}_2$  initiating system and iodine, in contrast, polymerized its vinyl group in polar solvents ( $\text{CH}_2\text{Cl}_2$  and nitroethane) highly selectively in the temperature range of  $-15$  to  $-40^\circ\text{C}$  to give soluble polymers with a polystyrene backbone and epoxy pendants; however, under these conditions, 10-15% of the epoxy groups of the polymers were consumed during the polymerization by the reaction with the growing species. The differences between the polymerizations of VPGE and p-isopropenylphenyl glycidyl ether, an  $\alpha$ -methylstyrene-type counterpart of VPGE, were also discussed with an emphasis on the effects of the  $\alpha$ -methyl group in the latter monomer. (Edited author abstract) 8 refs.

**081829 CATIONIC RING-OPENING POLYMERIZATION OF 2-SUBSTITUTED-2-OXAZOLINES INITIATED BY CARBON BLACK SURFACE.** Carbon blacks were found capable of initiating the ring-opening polymerization of 2-substituted-2-oxazolines at relatively high temperatures. The activation energy of the polymerization of 2-methyl-2-oxazoline was estimated to be  $13.4\text{ kcal/mol}$ . Carbon black lost the initiating activity of the polymerization upon the blocking of carboxyl groups on the surface by the treatment with potassium hydroxide or diazomethane. Therefore, it was concluded that carboxyl groups on carbon black play an important role in the initiation of the polymerization. Furthermore, it was found that during the polymerization, poly(N-acetylthyleimine) was grafted onto carbon black by the termination of growing polymer chain with the surface. (Author abstract) 12 refs.

**081830 DIMERIZATION OF THE METHYLVIOLOGEN CATION RADICAL IN ANIONIC MICELLAR AND POLYELECTROLYTE SOLUTIONS.** The dimerization behavior of the methylviologen cation radical ( $\text{MV}^{+}$ ) in the presence of sodium dodecyl sulfate (SDS), sodium decyl sulfate (SdecS), and sodium poly(styrenesulfonate) (PSS) was examined by using the visible spectral characteristics of solutions containing electrogenerated  $\text{MV}^{+}$ . The results indicate that the concentration of either SDS or SdecS micellar aggregates exerts a strong effect on the extent of dimerization. Thus, negligible dimerization was found at high levels of surfactant while extensive dimerization was observed at surfactant concentrations slightly above the corresponding critical micelle concentrations. This behavior was reasonably well simulated by a simple computational model based on the Poisson distribution. The dimerization

pattern in the presence of PSS was quite different. The polyelectrolyte was found to increase the dimerization level, throughout the entire concentration range surveyed (5-100 mM), over that found in isotropic aqueous solutions. This was interpreted as the result of MV<sup>+</sup> clustering triggered by the polyelectrolyte chains. (Author abstract) 16 refs.

**081831 MODELING OF DIFFUSION-CONTROLLED FREE-RADICAL POLYMERIZATION REACTIONS.** The present paper introduces a new fundamental approach to the modeling of diffusion-controlled free-radical polymerization reactions. Our analysis follows the original work of W.V. Chiu, G.M. Carratt, and D.S. Soong (CCS), according to which the termination and propagation rate constants are expressed in terms of both a purely reaction-limited term and a diffusion-limited one. The contribution of the latter term to the apparent rate constants is described in terms of the polymer and monomer effective diffusion coefficients and an effective reaction radius. It is shown that all parameters appearing in the original CCS model can be calculated from first principles using available data on the physical and transport properties of a particular monomer-polymer binary system. (Edited author abstract) 51 refs.

**081832 FRIEDEL-CRAFTS POLYMERS. 10. POLYCONDENSATION OF 4,4'-DICHLOROMETHYLDIPHENYL ETHER WITH PHENOL AND ISOMERIC CRESOLS.** Friedel-Crafts polycondensations of 4,4'-dichloromethyldiphenyl ether (DDE) with phenol and isomeric cresols were carried out under different experimental conditions. The molecular weight of the polymer products was estimated by end group analysis, that of soluble products by VPO, and they were characterized by TGA and solution viscosity. DMF solutions of samples prepared from phenol and p- and m-cresols, but not those from o-cresol, showed abnormal viscosity behavior. However, the viscosity behavior of DMF-water solutions was normal. Abnormal viscosity data of DMF solutions were correlated by an empirical relation. (Edited author abstract) 16 refs.

**081833 INVERSE GAS CHROMATOGRAPHY USED TO FOLLOW KINETICS OF EPOXY-AMINE REACTIONS IN THE MOLTEN STATE.** Polycondensation kinetics of epoxy-amine model systems were investigated with inverse gas chromatography. The results obtained were applied to the study of cross-linking kinetics of two epoxy prepolymers, tetraglycidyl diamino diphenyl methane and diglycidyl ether of bisphenol A, with diamino diphenyl sulfone. Data furnished by inverse gas chromatography showed zones of gelation and of vitrification. Based on kinetics established by isothermal microcalorimetry, it was possible to determine reaction advancement in these transition zones. The results show that advancement of both reaction systems to the transition points T<sub>1</sub> and T<sub>2</sub> is very sensitive to curing tempera-

ture and to the stoichiometry of the mixture. Finally, the vitreous transition temperatures of the cross-linked systems were determined and compared to those determined with differential scanning calorimetry. (Author abstract) 14 refs.

**081836 OPTIMAL STATE ESTIMATION IN THE TRANSESTERIFICATION STAGE OF A CONTINUOUS POLYETHYLENE TEREPHTHALATE CONDENSATION POLYMERIZATION PROCESS.** This paper describes an application of the extended Kalman filter algorithm to the state estimation of the melt transesterification stage of a continuous polyethylene terephthalate condensation polymerization process. When only two on-line measurements of reaction variables are used for state estimation, the prediction of reaction rates and product concentrations are unsatisfactory. When such limited on-line measurements are supplemented by five additional off-line measurements of various functional group concentrations, the system is completely observable and the overall performance of the state estimator is greatly improved. It has been shown that the analysis delay of 24 h is quite adequate for accurate state estimation of the process. In particular, the concentration of unwanted side product such as diethylene glycol (DEG) was predicted precisely. (Edited author abstract) 23 refs.

**081837 COPOLYMERIZATION OF CHLOROMETHYLSTYRENE AND DIVINYLBENZENE IN THE ABSENCE OR PRESENCE OF POLY(VINYL CHLORIDE).** Studies of the copolymerization of chloromethylstyrene (CMS) and divinylbenzene (DVB) were done in the presence of absence of poly(vinyl chloride) (PVC) in order to prepare anion-exchange membranes of excellent performance by the paste method. The copolymerization rate decreases when PVC is added and increases when the DVB quantity is increased in the presence of PVC. The copolymerization rate of the isomers of CMS and DVB increases in the following order: p-DVB > m-DVB > p-ethylvinylbenzene > p-CMS > m-CMS > m-ethylvinylbenzene. This order is not affected by the presence of PVC. The copolymerization of CMS and DVB takes place partially in PVC particles. (Author abstract) 17 refs.

**081838 COPOLYMERIZATION OF N-ARYLMALEIMIDES WITH METHYL METHACRYLATE.** The results of studies on the copolymerization of methyl methacrylates and three N-arylmaleimides are reported. The copolymerization was carried out in benzene at 70°C by using AIBN as initiator with a monomer-to-initiator ratio of 50. To determine the reactivity ratios, the copolymerization was carried out starting with different mole ratios of the monomers and stopping the reaction by adding an excess of methanol before 10% conversion. The reactivity ratios were determined by the Kelen-Tudos (KT) method. The T. Alfrey and C.C. Price parameters Q<sub>2</sub> and e<sub>2</sub> of the N-arylmaleimides were calculated by using the standard values of Q(0.74) and e(0.40) of MMA. 9 refs.

Kumar, Ajay (Cent for Cellular & Molecular Biology, Hyderabad, India). *J Macromol Sci Chem* v A24 n 6 1987 p 711-715.

**081839 ANALYSIS OF THE ROLE OF COMPLEX IN THE ALTERNATING COPOLYMERIZATION OF N-VINYLPYRROLIDONE AND MALEIC ANHYDRIDE.** Heterogeneous copolymerization of 1-vinyl-2-pyrrolidone (NVP) and maleic anhydride (MA) initiated with AIBN was studied in benzene at 60°C, at two different total monomer concentrations. The existence of a charge transfer complex between the comonomers has been shown and its equilibrium constant determined. The chemical composition of the copolymer was examined as a function of the initial monomer ratio, and it was found nearly equimolecular in a wide range of relative monomer concentrations. The compositional equation for the NVP/MA copolymerization system was derived with the consideration of the effect of the complex. (Edited author abstract) 19 refs.

**081840 POLYMERIZATION OF N-(P-AMINO-BENZOYL)CAPROLACTAM: BLOCK AND ALTERNATING COPOLYMERS OF AROMATIC AND ALIPHATIC POLYAMIDES.** The polymerization behavior of N-(p-aminobenzoyl)caprolactam was studied. It was found that polymerization could proceed by either elimination of caprolactam or by ring opening. Polymers prepared at temperatures above 200°C showed a greater tendency for ring opening to produce alternating aromatic/aliphatic copolymers than did polymers prepared at lower temperatures. Block copolymers of poly(p-benzamide) and nylon 6 were prepared by a two-stage hydrolytic polymerization process or by anionic polymerization

at temperatures  $> 200^{\circ}\text{C}$ . Polymer microstructures were determined using  $^{13}\text{C}$ -NMR spectroscopy by comparison with homopolymers and model alternating copolymers. (Edited author abstract) 12 refs.

**081841 MODEL COPOLYMERIZATION REACTIONS: EVIDENCE AGAINST PARTICIPATION OF A DONOR-ACCEPTOR COMPLEX IN REACTIONS OF THE 1-BUTYL RADICAL WITH N-PHENYLMALIMIDE AND STYRENE.** The participation of electron donor-acceptor (EDA) complexes in radical copolymerizations has been the subject of hundreds of research papers. Complex participation has been invoked to explain the formation of alternating copolymers, as well as the variations in overall copolymerization rate with changes in temperature, solvent, or monomer concentration, that are frequently observed in copolymerizations of donor (D) and acceptor (A) olefins. The essence of the complex-participation hypothesis is the idea that the growing polymeric radical 1 adds not only to the free olefinic monomers A and D, but also to an EDA complex 2 formed from them. The present paper addresses the reactions of styrene and NPM with the 1-butyl radical, a simple model for the propagating macroradicals involved in the styrene-NPM copolymerization. Specifically, the authors examine the possibility that this simple alkyl radical might undergo concerted addition to a 1:1 complex of styrene and NPM. 21 refs.

**081842 EQUILIBRIUM COPOLYMERIZATION. III. SEQUENCE DISTRIBUTION IN EQUILIBRIUM COPOLYMER.** The sequence distributions for the copolymers generated in three cases of binary equilibrium copolymerization, including the effect of the ultimate unit, are studied theoretically. From the equilibrium sequence distribution functions, the copolymer sequence structure, the number- and weight-average sequence lengths of monomer units, the run number, the randomness parameter, and the fractions of different diads in the copolymer are derived. According to the relation between the parametric variables introduced in the formulas and the equilibrium copolymerization conditions, all of the structural sequence parameters of the resulting copolymers can be predicted from the comonomer feed composition and the equilibrium constants for initiation and propagation. (Edited author abstract) 12 refs.

**081843 CATIONIC COPOLYMERIZATION OF 3-METHYLTETRAHYDROFURAN AND 3,3-DIMETHYLOXETANE: STRUCTURAL STUDY OF THE COPOLYMERS.** The bulk cationic copolymerization of 3-methyltetrahydrofuran and 3,3-dimethyloxetane was studied at  $0^{\circ}\text{C}$  using acetylhexafluoroantimonate as initiator. Values of the composition of the copolymers and the dyad and triad probabilities were obtained by  $^1\text{H}$ - and  $^{13}\text{C}$ -NMR spectroscopy. A kinetic scheme was proposed for this copolymerization and the values of the reactivity ratios were directly determined from the dyad probabilities. The experimental values of the triad probabilities were found to be in good agreement with those calculated from the reactivity ratios. (Author abstract) 23 refs.

**081844 COPOLYMERIZATION OF N-VINYLL-2-PYRROLIDONE AND 2-PHENYL-1,1-DICIANOETHENE.** Radical copolymerization of N-vinyl-2-pyrrolidone (NVP) with 2-phenyl-1,1-dicyanoethene (PDE) was studied in benzene at  $70^{\circ}\text{C}$ . Terminal, penultimate, and monomer complex participation kinetic models were applied to compositional data for

best prediction of the copolymer composition. Both penultimate and complex models described satisfactorily the deviation from the terminal copolymerization model, although the complex model did not predict as well as the penultimate model at high NVP/PDE monomer feed ratios. Copolymerization reactivity ratios indicated substantial effect of penultimate PDE monomer unit associated with polar repulsion of cyano groups. Equilibrium constant of NVP-PDE comonomer complex formation was found to be  $0.08 \text{ L/mol}$  as estimated by proton nuclear magnetic resonance (NMR) analysis of PDE's vinylic proton chemical shift upon complexation. Rate constants of propagation reactions were estimated by applying terminal complex copolymerization model. (Author abstract) 22 refs.

**081845 ALTERNATING COPOLYMERIZATION OF N-PHENYLMALIMIDE WITH CYCLOHEXYLVINYLBUTYRONE.** Complex formation between N-phenylmaleimide and cyclohexylvinylketone was studied by the proton magnetic resonance method (PMR), and the complex equilibrium constant was determined:  $K_c = 0.021 \text{ l./mole}$ . It was found that by radical copolymerization of the studied monomers, copolymers of equimolar composition are formed. By the 'shift of rate maximum' kinetic method, participation of donor-acceptor complexes in the chain-growth reaction could be quantitatively determined, and the statistical parameters of the N-phenylmaleimide-cyclohexylvinylketone copolymerization could be characterized. (Edited author abstract) 11 refs.

**081846 EMULSION POLYMERIZATION: THEORY OF PARTICLE SIZE DISTRIBUTION IN COPOLYMERIZATION SYSTEM.** A mathematical model for describing the particle size distribution (PSD) in emulsion copolymerization systems is developed by analogy to that in emulsion homopolymerization systems as proposed by Lichti and co-workers. By use of the appropriate combinations of the kinetic parameters of the comonomers, the complicated equations for copolymerization systems can be reduced to simpler equations identical to those of homopolymerization systems. The two calculation examples, styrene-methyl methacrylate and styrene-butadiene systems, are given to demonstrate the applicability of the proposed theory. The conditions for producing bimodal PSD from a seeded emulsion polymerization are discussed. (Author abstract) 20 refs.

**081847 HIGH-CONVERSION DIFFUSION-CONTROLLED COPOLYMERIZATION KINETICS.** Simultaneous polymerization of two or more monomers is a commercially important process for tailor making polymer properties. A major problem with this technique, however, is the well-known copolymer composition drift resulting from reactivity differences between the component monomers. During the course of copolymerization, the product formed becomes progressively depleted in the faster reacting monomer. In addition to intrinsic reactivity differences, diffusional processes exert a strong influence on the instantaneous molecular weight and possibly on the copolymer composition produced. The purpose of this work is to develop a high-conversion diffusion-controlled copolymerization model to predict the molecular weight and composition evolution. The model incorporates free-volume based diffusion theories of polymers as before in a homopolymerization model for high conversions. (Edited author abstract) 39 refs.

**081848 CYCLIZATION AND REDUCED REACTIVITY OF PENDANT VINYL DURING THE COPOLYMERIZATION OF METHYL METHACRYLATE AND ETHYLENE GLYCOL DIMETHACRYLATE.** Methyl methacrylate was copolymerized with small amounts of ethylene glycol dimethacrylate. Monomer and pendant vinyl conversion as a function of time was measured up to the gel point. Pendant vinyl conversion was determined by  $^1\text{H}$  NMR. Plots of pendant conversion versus monomer conversion exhibit a positive y-intercept indicating the tendency to cyclize during the formation of a primary chain. For bulk systems, this amounted to approximately 3-4% of pendant vinyls and the cyclic proportion increased with dilution. The slope of the pendant versus monomer conversion plot is attributed to the formation of cross-links and subsequent cycles. A kinetic model is developed which includes constants for cyclization and pendant reactivity. Values for these constants for the chemical systems studied are evaluated. The average pendant vinyl reactivity is found to be approximately half that of monomeric vinyl reactivity. (Author abstract) 21 refs.

**081850 EFFECTS OF SOLVENT POLARITY ON FREE RADICAL COPOLYMERIZATION OF 5-HEXENOIC ACID AND ACRYLONITRILE.** The effects of solvent polarity on free radical copolymerization of 5-hexenoic acid and acrylonitrile at  $60^{\circ}\text{C}$  were studied. It was observed that as the polarity of solvents enhanced, both the copolymerization rate and the reactivity ratios  $r_1$ ,  $r_2$  increased, while the alternating tendency of monomer units in the copolymer chain decreased. It is believed that the solvent polarity raises the reactivities of acrylonitrile monomer and its growing chain radical, but causes no distinct variation in those of 5-hexenoic acid. (Author abstract) 15 refs.

**081852 KOPOLIMERYZACJA ZWIĄZKÓW ALILIOWYCH Z BEZWODNIKIEM MALEINOWYM.** [Copolymers of Allylic Compounds and Maleic Anhydride]. On the basis of theoretical considerations concerning monomers capable of forming complexes with maleic anhydride, a general equation of copolymerization rate for such reactions has been derived, as well as its modifications for the case of an allylic monomer containing two double bonds of equal reactivity. An algorithm for the solution of these equations has been prepared, and on the basis of experimental results the values of rate constants of elementary reactions of chain growth in the system bis(allylcarbonate) of diethylene glycol (monomer 1)-maleic anhydride (monomer 2) have been determined. The knowledge of these values makes it possible for the first time to consider the participation of each elementary stage of chain growth in the overall rate of the process. **081854 POLYMERIZATION AND COPOLYMERIZATION OF N-ALLYLCITRACONIMIDE.** Homopolymerization and copolymerization of N-allylcitraconimide (ACI) were carried out at 60°C by using azobisisobutyronitrile as an initiator. The initial overall rate of polymerization was proportional to the square root of the initiator concentration. The overall activation energy measured was 23.7 kcal/mol. In the copolymerization of ACI ( $M_1$ ) with styrene ( $M_2$ ), alternating-type copolymers were obtained. All the citraconyl groups participated in copolymerization and all the allyl groups remained as residual double bonds. The reactivity ratio was determined. (Edited author abstract) 22 Refs. ## Electrolytic

**081856 ELECTROINITIATED JOINT POLYMERIZATION OF PHENYL ISOCYANATE AND METHYL METHACRYLATE.** It is seen from the presented experimental data that phenyl isocyanate (PI) is the more active monomer upon electrochemically initiated polymerization of a mixture of PI with methyl methacrylate (MMA), which is associated with the easier reduction of the isocyanate group, in comparison with the unsaturated MMA bond. The half-wave potential for PI is equal to 1.54 V, while it is 1.78 V for MMA; therefore, isocyanate groups participate primarily in the growth reaction. Upon electrochemical polymerization reduction at the isocyanate group occurs at a more positive potential with formation of TPI, after precipitation of which the PI concentration in solution falls to 0.3-0.4 mole/l. The first fractions of PI and MMA copolymer (fraction II) are still enriched with PI, in comparison with the composition of the initial reaction mixture, and then at later stages of the reaction, when PI is significantly depleted, its content in the copolymer decreases to several percent. 14 refs.

## Equipment

**081857 MOLECULAR MASS DISTRIBUTION IN ISOTHERMAL RADICAL POLYMERIZATION IN A CASCADE OF IDEAL MIXING REACTORS.** The macrokinetics of initiated radical polymerization in a cascade of ideal mixing continuous reactors is described. The degree of polymerization and the MMD (Molecular Mass Distribution) range are analyzed as a function of the effective polymerization and initiation constants and of the reaction mixture feed rate. It is shown that within the technological region of change of the parameters the degree of polymerization is decreased along the cascade steps. A non-steady change in the degree of polymerization and in the MMD range with change in reagent consumption is observed. (Author abstract) 5 refs.

**081858 EFFECT OF HYDRODYNAMIC FACTORS ON MOLECULAR-WEIGHT DISTRIBUTION DURING FREE RADICAL POLYMERIZATION IN A SCREW REACTOR.** The process of free-radical polymerization in a screw reactor is considered together with an account of the viscosity of the reacting medium as a function of temperature, monomer conversion, and weight-average degree of polymerization. It is shown that the relationship between the molecular-weight distribution and macro-kinetic factors leads to new laws for the process. The author shows that large energy dissipation leads to a strengthening of the anisothermality of the process and a fall in the polymerization degree of the reaction product. The viscosity is considerably depressed, the pressure drop across the reactor is significantly reduced, and the form of the  $\Delta p(q)$  curve may be changed. 14 refs.

## Heat Transfer

**081859 HEAT TRANSFER DURING POLYMERIZATION IN MOTIONLESS MIXERS.** Investigation of

the performance of a large-diameter conventional motionless mixer used as a continuous reactor for styrene polymerization showed that it behaved adiabatically. Computer simulation (in which the mixer is treated as an ideal plug-flow reactor having perfect radial mixing) predicts this tendency in terms of axial temperature profile. To avoid adiabatic polymerization, with its attendant problems of plant operability and polymer quality, the use of motionless mixers having internal heat transfer surface is indicated. **081862 MODELING OF BATCH AND CONTINUOUS EMULSION POLYMERIZATION REACTORS. PART I: MODEL FORMULATION AND SENSITIVITY TO PARAMETERS.** A detailed model for the prediction of the behavior of batch or continuous emulsion polymerization reactors has been formulated, and an efficient numerical scheme for simulation developed. The model makes use of population balance equations and detailed mechanisms for chemical and physical rate processes. The numerical procedure chosen for its solution is orthogonal collocation on finite elements. In this paper, a few comparisons with experimental data are presented to demonstrate the model validity. Finally, a parametric sensitivity study is carried out to identify the most important kinetic and physical parameters. In the sequel, a comprehensive comparison of model predictions with a wide variety of experimental data will be presented. (Author abstract) 91 refs.

**081863 MODELING DIFFUSION AND REACTION IN EPOXY-AMINE LINEAR POLYMERIZATION KINETICS.** Three mathematical models of reaction and diffusion in linear addition polymerizations were developed and compared to experiments with n-butylamine (NBA) and the diglycidyl ether of bisphenol A (DGEBA). The first model served as a control and was

based on the standard approximation that a single rate constant holds for reaction between all species at all levels of polymerization. In the second model, a single but average rate constant was a function of the number- and weight-averaged molecular weights. Finally, the third model replaced this single, globally averaged rate constant with a matrix of rate constants accounting for the reactions of individual molecular species. Experimental kinetics data, obtained through FTIR, GPC, and DSC analyses, aided in model discrimination. Either model 2 or 3 provides a suitable account of the influence of diffusion limitations on linear polyaddition reactions. (Author abstract) 19 refs.

**081867 PHOTOINDUCED POLYMERIZATION AND OLIGOMERIZATION OF 4-VINYLBEN-**

**ZOPHENONE.** The photopolymerizations of 4-vinylbenzophenone (VBP) in various solvents were investigated to make clear the photoinitiation characteristics. It was found that direct photoirradiation produces polymers, oligomers (trimers), and dimers. The dimers were identified as trans- and cis-1,2-bis(4-benzoylphenyl)cyclobutanes. The fraction of trans-form in the cyclobutane dimers produced was about 80%, and was little affected by the reaction conditions. The quantum yields [VBP] = 0.1M in benzene) were estimated to be  $3 \times 10^{-2}$  for the dimerization and  $2 \times 10^{-4}$  for the initiation of polymerization. The photoreactions via  $\pi, \pi^*$  triplet state of the monomer were suggested from the results. (Author abstract) 14 refs.

**081868 RADIATION POLYMERISATION OF CYCLOHEXYL METHACRYLATE - I.** Radiation polymerization of cyclohexyl methacrylate has been carried out at various doses, dose rates and temperatures. The radical yield determined by induction period method using benzoquinone as a scavenger is 6.25. The dose rate exponent is found to be 0.517 indicating a bimolecular termination. The  $(K_p/K_t^{1/2})$  value is 0.268, which is an order of magnitude higher than for methyl methacrylate under identical conditions of dose rate and temperature. Energy of activation calculated on the basis of kinetic data is found to be 2.06 kcal/mol, which is also quite low. These results indicate the probability of the existence of an anionic initiation in addition to free radical initiation. (Edited author abstract) 14 refs.

Kumar, Manmohan (BARC, Bombay, India); Rao, M.H.; Rao, K.N. *Radiat Phys Chem* v 30 n 1 1987 p 21-25.

**081869 RADIATION POLYMERISATION OF CYCLOHEXYL METHACRYLATE - II. ROLE OF IONIC AND RADICAL SCAVENGERS.** Radiation polymerization of cyclohexyl methacrylate has been carried out in the presence of scavengers, i.e., biphenyl, cyclohexanol and benzoquinone. In the presence of biphenyl and cyclohexanol which are scavengers for electrons and anions no induction period was observed and the rates of polymerization and molecular weights decreased to the same extent. In presence of benzoquinone, a scavenger for both anions and free radicals, an induction period was observed, decreasing both the molecular weights and the rates of polymerization. From these results it is evident that the polymerization takes place both by anions and free radicals. A very high chain transfer constant to benzoquinone equal to 23.06 was obtained. (Edited author abstract) 5 refs.

**081870 CHARACTERISTICS OF POLYMER MICROSPHERES PREPARED BY RADIATION-INDUCED POLYMERIZATION IN THE PRESENCE OF ORGANIC SOLVENTS.** Radiation-induced polymerization of diethylene glycol dimethacrylate (2G) was carried out in methyl orthoformate (MOF) in the range of 25 to  $-78^\circ\text{C}$ , to obtain the polymeric microspheres. A transparent solution consisting of 2G and MOF showed an emulsified state after irradiation. This means that the colloidal particles of poly(2G) are deposited from monomer solution during the irradiation because of poor solubility. It was confirmed by microscopic observation that the shape of obtained polymer is composed of a complete sphere. The preparation of poly(2G) microspheres was further tried using various organic solvents under such conditions as 10 kGy and  $25^\circ\text{C}$ . According to this experiment, poly(2G) microspheres of the smallest size were obtained in the presence of ethyl caproate, while

the largest size was obtained when tetrahydrofuran was used. (Edited author abstract) 13 refs.

Yoshida, Masaru (JAERI, Takasaki, Jpn); Asano, Masaharu; Kaetsu, Isao; Morita, Yasushi. *Radiat Phys Chem* v 30 n 1 1987 p 39-45.

**081871 NEW FUNCTIONAL MICROSPHERES WITH ACTIVE SUCCINIMIDE GROUPS.** Radiation-induced polymerization of monomers, for example N-methacryloxysuccinimide (MASu) and diethylene glycol dimethacrylate (2G), in ethyl propionate, was performed from  $+25^\circ\text{C}$  to  $-78^\circ\text{C}$ . The copoly(MASu/2G) microspheres were obtained in MASu monomer compositions of 30 wt% or below. The average particle diameter of copoly(MASu/2G), 20/80 wt% microspheres obtained at irradiation temperatures of  $25^\circ\text{C}$ ,  $0^\circ\text{C}$ , and  $-43^\circ\text{C}$  were  $0.81 \pm 0.29$ ,  $0.63 \pm 0.26$ , and  $0.90 \pm 0.43$   $\mu\text{m}$ , respectively. No microspheres were formed when irradiated at  $-78^\circ\text{C}$ . The reactivity of the succinimide groups on the surface of copoly(MASu/2G, 20/80 wt%) microspheres was checked by reacting with ethylene diamine. The maximal amounts of reacting succinimide groups was  $9.4 \pm 0.5$   $\mu\text{mol/g}$ , which corresponds to about 1% of the total number of succinimide groups in the microsphere. (Author abstract) 23 refs.

**081872 MECHANISTIC ASPECTS OF POLYMER CHEMISTRY FOR RADIATION CURING.** The chemistry of polymer production has been reviewed for the purpose of identifying suitable uses for high-energy electron accelerators in the plastics industry. High-energy radiation produces free radicals, electrons and ions in irradiated materials. These species initiate polymerization and cross-linking reactions in a manner analogous to that of chemical agents. The chemical mechanisms of radiation-induced polymerization, co-polymerization and cross-linking are compared with those of chemical and thermal initiation. Radiation polymerization can be a very fast process, but the polymerization reactions are quite exothermic, and temperature increases of up to  $400^\circ\text{C}$  may result if insufficient cooling is provided. Several approaches to reducing the temperature increase during radiation curing are presented. Chemical kinetic simulations of the radiation-induced cationic polymerization of styrene have shown that the effect of water inhibition on the rate of polymerization may be eliminated at the high dose rates available from high power accelerators. (Author abstract) 25 refs.

**081873 POLYMERIZATION UNDER ELECTRON BEAM: STABILITY PROBLEM OF GRAFTED POLYMER SYSTEMS.** In order to clarify the stability of grafted polymer systems the permeability and diffusion coefficient of low-molecular substances have been investigated as a function of temperature and organic solvent attacks. It is shown that the stability of some grafted acrylic polymers can be improved significantly by varying the irradiation regime and preliminary cross-linking of the polyethylene matrix. (Author abstract) 3 refs.

**081874 SYNTHESIS OF POLYMER MATERIALS BY LOW ENERGY ELECTRON BEAM. IV. EB-POLYMERIZED URETHANE-ACRYLATE, -METHACRYLATE AND -ACRYLAMIDE.** Electron beam (EB)-processing has the advantages of high production efficiency and low energy cost. In this study, the effects of EB-reactive terminal group on the structure and properties of EB-reactive urethane prepolymers and their

EB-polymerized polymers were examined, considering the characteristics of EB solid-state polymerization. Three kinds of urethane prepolymers with different terminal groups, that is, urethane-acrylate, -methacrylate and -acrylamide were synthesized for this purpose. It is reported that terminal groups strongly influence the phase structure and tensile properties of the prepolymers and EB-polymerized polymers. 13 refs.

**081876 INFLUENCE OF MATRIX POROSITY ON THE IMMOBILIZATION OF PENICILLIN ACYLASE BY RADIATION-INDUCED POLYMERIZATION.** Penicillin acylase was immobilized by low temperature gamma radiation-induced polymerization into polymer matrices obtained from monomers of different hydrophilicities, at various ratios of monomer to enzyme solution and at different polymerization conversions. It was found that the penicillin acylase retention (60-85% of the starting enzyme) is independent of the monomer used in the polymerization, of the polymerization conversion and of the porosity of the polymer matrix. On the other hand, the penicillin acylase retention strongly depends on the presence in the irradiation mixture of the hydrophobic crosslinking agent, trimethylolpropane trimethacrylate, even in small amounts. The data suggest that the enzyme is bound to the polymer matrix by hydrophobic interactions through crosslinking agent molecules. (Author abstract) 8 refs.

**081878 RADIOLYTIC METHOD OF PREPARATION OF SEMICONDUCTOR ASSEMBLIES SUPPORTED ON POLYMERIC MEMBRANES.** Radiation induced grafting of hydrophilic acrylic monomers onto polymeric films and fabric has been employed to prepare supports for catalytic assemblies, which are highly permeable to water and low molecular weight solutes. Transition-metal-oxide semiconductor clusters embedded within the grafted membranes were formed by swelling the

membranes with a solution of metal alkoxides followed by gradual hydrolysis. Photolytic methods have been employed to form  $Pt^0$  clusters onto the semiconductor aggregates. Kinetic aspects of the radiation induced grafting of the polymeric supports and the mechanistic features of the preparation of polymer-anchored  $TiO_2$  clusters loaded with  $Pt^0$  are described. The photocatalytic effectiveness of the  $TiO_2$ - $Pt$  assemblies embedded in recoverable polymeric grids was demonstrated in hydrogen generation from aqueous solution and in the degradation of environmental pollutants. **081879 RING-OPENING POLYMERIZATION.** This three-volume book with 14 papers provides a comprehensive survey of the field of ring-opening polymerization. Topics include: thermodynamic and mechanistic features of ring-opening polymerization; polymerization of cyclic compounds containing only carbon atoms in the ring; various types of heterocyclic monomers where the heteroatom may be oxygen, nitrogen, phosphorus, sulfur, and silicon. Three general topics are explored throughout the book: the exploration of new catalysts; the elucidation of mechanisms; and the characterization of products.

**081880 KINETIC STUDY ON THE POLYMERIZATION REACTION INITIATED BY AROMATIC TERTIARY AMINE AND BENZYL CHLORIDE.** A binary mixture of N,N-dimethylaniline (DMA) and benzyl chloride ( $BzCl$ ), or ammonium salts of such compounds, are capable of initiating free radical polymerization reactions of vinyl monomers. Such initiating techniques had been employed for modifying cellulose through graft copolymerization reactions. Further investigation was conducted on the initiative characteristics of such a system. A dilatometric method was used to measure the polymerization rate ( $R_p$ ) of methyl methacrylate (MMA) (degassed under high vacuum) in benzene solvent at 60°C. The effects of substituted groups at the benzene ring of DMA on the polymerization rate were also studied. It is found that when the electron-withdrawing groups were attached on the benzene ring of DMA, then the  $R_p$  of MMA initiated by them would drop. The effects of such electron-withdrawing groups could be described by the Hammett equation. (Edited author abstract) 10 refs. In Chinese.

**081881 KINETICS OF POLYURETHANE FORMATION IN POLYURETHANE-POLY(METHYL METHACRYLATE) INTERPENETRATING POLYMER NETWORKS.** The kinetics of formation of polyurethane in polyurethane/ poly(methyl methacrylate) interpenetrating polymer networks (IPNs) were investigated by Fourier transform infra-red spectroscopy. The influence of different parameters was examined: catalyst concentration, polyurethane content in the IPNs, reaction temperature. It was found that the overall reaction rate is related to the concentration of isocyanate by a 1.5th order exponential expression for the catalyzed polyurethane formation. (Author abstract) 19 refs.

**081882 MONTE CARLO ESTIMATION OF KINETIC PARAMETERS IN POLYMERIZATION REACTIONS.** A general method for estimating kinetic parameters in polymerization reactions using Monte Carlo simulation to represent the models of the reactions is developed. From a statistical point of view, the procedure is a Bayesian one in which a posterior probability density surface (PPDS) is calculated for points on a grid in the parameter space. A smoothing function is fitted to the PPDS, then a posterior probability region, which is similar to a confidence region, is calculated for the parameters. An application to a relatively trivial example, the Mayo-Lewis copolymerization model, is shown in detail. Many other potential applications are suggested. (Author abstract) 15 refs.

**081885 MINIMUM END-TIME POLICIES FOR BATCHWISE RADICAL CHAIN POLYMERIZATION: THE PIECEWISE INITIATOR ADDITION POLICY.** For the radical chain polymerization in a presence of chain transfer agent, piecewise initiator addition and piecewise reaction temperature are considered as two control actions in N unequal time intervals for minimizing the total reaction time under a given final monomer conversion and the number average chain length. It is found that only one of the two actions are needed to be chosen in the bulk or solution polymerization without chain transfer agent. The initiator addition control is found to be better than the temperature control at the expense of lower polydispersity. The optimal policy of the piecewise initiator addition under the best isothermal temperature is that which gives the highest possible reaction temperature and the least possible total amount of initiator charged just enough for the polymerization to reach the predetermined number average chain length and conversion. (Edited author abstract) 12 refs.

**081886 KINETIC STUDY ON MMA POLYMERIZATION INITIATED BY A TRI-COMPONENT SYSTEM OF DIMETHYLANILINE-BENZYL CHLORIDE-ACETIC ACID.** The radical polymerization of MMA can be accomplished by the initiation of N,N-dimethylaniline (DMA)-benzyl chloride (BC)-acetic acid (HAc) tri-component system. HAc in the mentioned system plays the role of catalyst and which will reduce the activation energy of polymerization notably. The overall apparent activation energy of this system  $E_a$  is 36.8 kJ/mol. Under the same reaction conditions, the polymerization rate is faster than that in DMA-BC-MMA system by one order of magnitude. The molecular weight of polymer is inversely proportional to  $[I]^{1/2}$  and temperature. The results are in good agreement with the performance of radical polymerization. It has been found experimentally that any oxygen present will bring certain rather complicated but remarkable effects upon the polymerization of the given system. From these experimental results, the mechanism of initiating reaction of DMA-BC-HAc system was discussed. (Edited author abstract). 11 Refs. In Chinese.

**081887 PARTICLE FORMATION IN EMULSION POLYMERIZATION: TRANSIENT PARTICLE CONCENTRATION.** A general kinetic model of particle formation in emulsion polymerization is presented. This model takes into account homogeneous, micellar, and monomer droplet nucleation mechanisms. Chain transfer and termination in the aqueous phase, capture of oligomer radicals by particles, and coagulation of particles are also considered. A three-parameter analytical solution is obtained. The model parameters  $N_s$ ,  $A_2$ , and  $\tau$  can be estimated from basic kinetic parameters and reaction conditions. Model predictions are in agreement with experimental data obtained from the literature. (Edited author abstract). 49 Refs.

**081888 EMULSION POLYMERIZATIONS. II. KINETICS, MOLECULAR WEIGHT DISTRIBUTIONS, AND POLYMER MICROSTRUCTURE OF EMULSION COPOLYMERS.** The kinetics of emulsion copolymerizing systems during intervals II and III (i.e., after completion of latex particle formation) has been studied through the pseudo-homopolymerization approach. The Smith-Ewart equations for copolymers are reduced to the corresponding equations for homopolymers by introducing suitable pseudo-homopolymerization parameters. Analogies and differences between our results and those of previously reported treatments are critically discussed. Explicit algebraic relationships are reported for both the two-dimensional molecular weight distribution and the unidimensional marginal distribution functions of molecular weight and chemical composition. (Edited author abstract). 38 Refs.

**081889 ESTIMATION OF THE MOLECULAR WEIGHT DISTRIBUTION IN BATCH POLYMERIZATION.** A filtering technique is proposed for on-line estimation of the temperature, monomer conversion, initiator conversion, and the entire molecular weight distribution in a batch methyl methacrylate polymerization reactor. The technique uses a detailed polymerization model combined with on-line measurements of conversion, temperature, and the molecular weight distribution, taken at different discrete time intervals. The polymerization model includes a chain-length-dependent termination rate constant which allows the prediction of the molecular weight distribution for common free-radical polymerization conditions. Comparisons between modeling and experimental results show that the polymerization model gives good predictions of the monomer conversion and the

molecular weight distribution in the polymerization system. The performance of the estimation scheme is tested for cases of strong gel effect conditions leading to a bimodal molecular weight distribution, and poor initial conditions. Finally, off-line experimental data are used to test the algorithm under actual reactor operating conditions. (Author abstract). 39 Refs.

**081890 POLIMERIZAREA CLORURII DE VINIL IN PREZENTA DIALILMALEATULUI.** [Polymerization of vinyl chloride in the presence of diallylmaleate]. A small addition of diallylmaleate (DAM) (0.02-0.03 percent of the monomer quantity) in the suspension or emulsion polymerization medium of the vinyl chloride enhances Fikentscher's K value and increase the molecular mass distribution as well as the  $M_w/M_n$  polydispersion degree. The efficiency of increasing the molecular masses depends on the polymerization conditions (temperature, DAM concentration and impurities in the system) and on the nature of the process (suspension or emulsion). The DAM molecule is supposed to be linked with both allylic ends to the growing molecular chains, accompanied by the formation of two inactive radicals incapable of continuing the polymerization reaction. The mechanism explains the decrease of the polymerization rate in the presence of DAM quantities larger than the optimal ones, and the standstill of the K value growth. (Edited author abstract). 3 Refs. In Romanian.

## Research

**081891 STUDIES ON TEMPLATE POLYMERIZATION.** In recent years, polymerization of monomer molecules organized in various ways has been studied in the crystalline state, as mono- and multilayers, in oriented aggregates in solution, as clathrates, in the liquid-crystalline state, and on templates. The templates are linear polymer molecules carrying groups which interact with monomer molecules, ideally to produce a predetermined linear array of the latter. This review is an account of the progress made in the field of template polymerization for the last 20 years. In template polymerization we seek to achieve polymerization of monomer units attached to a template in a predetermined manner and thus to synthesize polymers or copolymers having precise structures and microstructures complementary to those of the template. The three component steps in template polymerization are: template monomer complexation, template polymerization and, separation of the template from daughter polymer. 38 refs.

**081892 CONTINUOUS MINIEMULSION POLYMERIZATION.** The authors examine the basic elements of both emulsion polymerization and suspension polymerization. In addition, the kinetics of miniemulsion polymerization are also discussed. Stabilization effects are also studied. The effect of cosurfactants and gels is outlined. 17 refs.

Barnette, Darrell T. (Georgia Inst of Technology, Atlanta, GA, USA); Schork, F. Joseph. *Chem Eng Prog* v 83 n 6 Jun 1987 p 25-30.

**081893 EFFECT OF IMPURITIES IN CONTINUOUS 'LIVING' ANIONIC POLYMERIZATIONS.** The aim of this work is to theoretically investigate the effect of impurities on the MWDs of the polymers produced when anionic polymerizations are carried out in SS and periodic CSTRs. The effect of impurities contained in the monomer feed is theoretically investigated, in relation to 'living' anionic homopolymerizations carried

out in isothermal and homogeneous CSTRs. In the SS operation, the total produced polymer always exhibits a Schulz-Flory distribution, with a NACL which decreases as the impurities are increased. The result is reasonable bearing in mind that the system is dynamically equivalent to a continuous free-radical polymerization with initiation, propagation and termination by disproportionation. 10 refs.

**081894 NONTERMINATED CHAIN POLYMERIZATION IN A CONVECTIONLESS GAS.** We have investigated the steady-state distribution, with respect to degree of polymerization and location within the reaction chamber, of polymeric radicals produced by a gas-phase free radical chain reaction, under the following conditions. Initiating free radicals are produced, uniformly and at a constant rate, throughout a uniform monomer vapor in a reaction chamber in which the gases are free of convection, and the concentration of radicals is so low that recombination termination is absent. The free radicals propagate into polymeric radicals which diffuse to the walls of the chamber where they are irreversibly adsorbed. (Edited author abstract) 6 refs.

Rabeony, H. (Univ of California, Los Angeles, CA, USA); Reiss, H. *Macromolecules* v 21 n 4 Apr 1988 p 912-918.

**081895 MICRODISPERSIVE INTERFACIAL MIXING IN FAST POLYMERIZATIONS.** Interfacial activity between liquid reaction injection molding (RIM) reactants was observed using light microscopy. Diisocyanates were brought into contact with various diols and diamines in a thin (250  $\mu$ m) gap. A dynamic phenomenon, rapidly producing a well-mixed, intermaterial phase, was discovered. It was revealed that the rate of growth of this newly formed region was dependent on both the rate of reaction and the physical properties of the initially formed product species at the reaction interface. Spontaneous interfacial mixing also occurred without chemical reaction when a reaction product was dissolved in 'capped' contacting reactant liquids. It is believed that strong interfacial intermolecular forces, inducing flow through the polymerization product layer formed immediately upon reactant contact, are responsible for the initial explosiveness of this microscopic process. (Edited author abstract). 22 Refs.

**081896 TERMINATION IN FREE-RADICAL POLYMERIZING SYSTEMS AT HIGH CONVERSION.** A theory for the termination rate coefficient in high-conversion free-radical polymerization systems, based on the concept of chain-end diffusion by propagational growth ('reaction diffusion' or 'residual termination' mechanism), is proposed. This is used to formulate the appropriate diffusion coefficient of a macroradical, which yields in turn a diffusion-controlled termination rate coefficient. Expressions for an upper and lower bound of this rate parameter result, depending on whether the polymer chains are rigid or dynamically flexible. All parameters used in the model (such as entanglement spacing and unperturbed chain dimensions) can be readily determined. (Edited author abstract). 45 Refs.

Russell, Gregory T. (Univ of Sydney, Sydney, Aust); Napper, Donald H.; Gilbert, Robert G. *Macromolecules* v 21 n 7 Jul 1988 p 2133-2140.

**081897 INITIATOR EFFICIENCIES IN HIGH-CONVERSION BULK POLYMERIZATIONS.** By consideration of relative rates of diffusion and of propagation, it is shown that, in some bulk polymerizations, there exists a certain weight fraction of polymer ( $w_p$ ) beyond which initiator efficiency ( $f$ ) must rapidly

decrease. At this critical  $w_p$ , the two free radicals formed from initiator decomposition are immobilized by propagation faster than they can diffuse apart; consequently, their likely fate is to become trapped in close proximity to each other and undergo geminate recombination. A quantitative theory for the onset of this phenomenon is derived. (Edited author abstract). 26 Refs.

Russell, Gregory T. (Univ of Sydney, Sydney, Aust); Napper, Donald H.; Gilbert, Robert G. *Macromolecules* v 21 n 7 Jul 1988 p 2141-2148.

**081898 LIMITING STAGE OF SORPTION AND DESORPTION PROCESSES OF RADICALS BY PARTICLES IN EMULSION POLYMERIZATION.** The equilibrium, diffusional, and kinetic approaches to determining the limiting stages of processes of sorption and desorption of free radicals by micelles and latex particles are considered. Analysis of available data indicates that the assumption that the rate of the sorption and desorption processes are limited by resistance to mass transfer at the particle-water interface is applicable, i.e. that the kinetic approach is applicable. (Author abstract). 31 Refs.

Lukhovitskii, V.I. (L. Ya. Karpov Physicochemical Inst, USSR). *Polym Sci USSR* v 29 n 4 1987 p 960-967.

**081899 EFFICIENT ALGORITHM OF COMPUTATION OF MOLECULAR WEIGHT DISTRIBUTIONS AND ITS MOMENTS FOR REVERSIBLE STEP GROWTH POLYMERIZATION IN HOMOGENEOUS CONTINUOUS FLOW STIRRED TANK REACTORS.** The reversible step growth polymerization in homogeneous continuous flow stirred tank reactors (HCSTRs), in which the condensation product (W) leaves the reactor through flashing, has been analyzed. The molecular weight distribution (MWD) of the polymer formed is governed by nonlinear coupled algebraic relations to be solved simultaneously. To find the MWD numerically a large number of these algebraic relations are normally solved simultaneously using a suitable iterative procedure. These have been decoupled using the technique proposed in earlier works and the MWD can now be obtained sequentially without any trial and error. This leads to considerable saving in computation time compared to methods currently used. (Edited author abstract). 33 Refs.

## Solutions

**081900 USE OF LOW TEMPERATURE OZONOLYSIS FOR DETERMINING THE DEPTH OF POLYMERIZATION IN SOLUTION.** The use of the method of low temperature ozonolysis is proposed for determining the heat of polymerization of vinyl monomers in solutions active to ozone at 273 K. The heat of polymerization of methyl methacrylate in 50% benzene is 58.82 kJ/mole. According to four measurements obtained, the mean values of the extent of polymerization and heat evolution are  $99.63 \pm 0.04\%$  and  $569.57 \pm 9.2$  J/g respectively, which enables the heat of polymerization  $q = 57.23 \pm 0.96$  kJ/mole to be calculated. This value is close to the value found in the polymerization of MMA in bulk, i.e.,  $q = 58.82 \pm 0.67$  kJ/mole, which confirms the published data on the absence of anomalies in the polymerization of MMA in benzene. (Edited author abstract) 4 Refs.

## Spectrum Analysis

**081901 USE OF A FLUORESCENCE METHOD FOR ASSESSING THE PROPERTIES OF POLYMERS AND THEIR COMPOSITES AND FOR ADAPTING THEIR PRODUCTION TECHNOLOGY.** Correlation of relaxation and diffusion processes in polymers and their composites with the kinetic patterns shows the possibilities of the fluorescence method for

monitoring the process of polymerization of polymeric composites, and hence for adapting their production technology. Analysis of relaxation and diffusion processes in polymeric composites reveals the possibilities of using the fluorescence method not only for assessing their structural features (micrononhomogeneity, stratification) and physical properties such as microviscosity, but also to follow their evolution in the course of the polymerization process. 11 Refs.

## Stabilizers

**081902 PARTICULATE STABILISERS FOR DROPS IN SUSPENSION POLYMERISATION: USE OF A WAX MODEL.** Finely divided inorganic solids can be used for drop stabilization in suspension polymerization. In order to clarify the role of these solids, experiments have been carried out using a model system in which wax drops were dispersed in water in the presence of magnesium hydroxide. Drop sizes were reduced if the hydroxide was precipitated in situ before dispersion of the wax. As the loading of this precipitate increased, the average drop size passed through a minimum. The presence of a surfactant modified the effect of the hydroxide. (Edited author abstract) 14 Refs.

## Theory

**081903 KINETIC THEORY ON CATIONIC POLYMERIZATION WITH TERMINATION BY COMBINATION WITH A NEGATIVE FRAGMENT.** The cationic polymerization with instantaneous initiation and termination by combination with a negative fragment, which is the product formed during initiation reaction with some component of the polymerization system, has been studied by means of a non-steady-state method. The molecular weight distribution function and a series of important molecular parameters of the polymer generated from mono-bi-, and multifunctional initiators are rigorously derived. The theoretical results obtained are applicable to any ionic polymerization with second-order termination. A procedure is described for calculating the molecular weight distribution curve and the values of the various molecular parameters directly from the polymerization conditions. (Author abstract) 37 Refs.

Cai, Gang-Feng (Case Western Reserve Univ, Cleveland, OH, USA); Yan, De-Yue; Litt, Morton. *Macromolecules* v 21 n 3 Mar 1988 p 578-584.

**081904 MOLECULAR WEIGHT DISTRIBUTION AND MOMENTS FOR CONDENSATION POLYMERIZATION WITH VARIANT REACTION RATE CONSTANT DEPENDING ON CHAIN LENGTHS.** A new model for the chain length dependence of the reaction rate constant is proposed for the molecular weight distribution and averaged molecular weights obtained in linear condensation polymerization. An infinite molecular weight for a finite time is predicted if the reaction rate constant is increasing with chain length. The moments method is used and Gupta's model is reconsidered for analytic solutions. Both models are compared with available experimental data. (Author abstract) 7 Refs.

Park, O Ok (Korea Advanced Inst of Science & Technology, Seoul, South Korea). *Macromolecules* v 21 n 3 Mar 1988 p 732-735.

Thermodynamics See Also OLEFINS—Polymerization.

**081905 GENERAL THERMODYNAMIC AND MECHANISTIC ASPECTS OF RING-OPENING POLYMERIZATION.** In order to illustrate the operation of both thermodynamic and kinetic restrictions on ring-opening polymerizations, the polymerizability of the cycloalkanes and cycloalkenes is considered. The standard free energy change associated with any ring-opening polymerization is made up of an enthalpy term and an entropy term. The values of these two terms are determined by a number of chemical and physical factors which are described along with other thermodynamic aspects in the ring-chain equilibria, copolymerization, ionic and radical mechanisms, and metallocarbene intermediates. 228 Refs.

Ivin, K.J. (Queen's Univ of Belfast, North Irel); Saegusa, T. *Ring-Opening Polym* v 1. Publ by Elsevier Applied Science Publ, London, Engl and New York, NY, USA, 1984 1-81.

**081906 RING-OPENING POLYMERIZATIONS VIA CARBON-CARBON  $\sigma$ -BOND CLEAVAGE.** The relief of strain energy realized upon formation of an acyclic polymer from strained ring monomers can provide a thermodynamic driving force for polymerization. Unfortunately, carbon-carbon  $\sigma$ -bond cleavage is usually associated with a high energy of activation. Researchers in this area have attempted to find ways in which carbon-carbon  $\sigma$ -bond cleavage in strained rings can occur cleanly so as to form polymers. In this review the mechanistic insights available from the physical organic chemical literature are used to interpret the observed polymer chemistry of carbon-carbon bond cleavage. 83 Refs.

**081907 INFLUENCE OF CHEMICAL STRUCTURE ON NONELASTIC MECHANICAL PROPERTIES IN POLYSTYRYL-PYRIDINE RESINS.** We propose a micromechanical characterization of the chemical structure (i.e., the state of cure) of polystyryl-pyridine (PSP) resin. The nonelastic work-hardening rate  $K$  is measured in the preyield stage during compression tests at constant strain rate. The nonelastic deformation is analyzed from a metallurgical point of view; the parameter  $K$  varies as the inverse of the nucleation rate for dislocations and thus is a measure of the ability of the material to deform plastically. The comparison with high-resolution

solid-state carbon-13 NMR experiments shows that, at room temperature, the ability of PSP resin to deform plastically depends mainly on the degree of crosslinking, whatever the length of prepolymer molecule; however, at high temperatures ( $T=200^{\circ}\text{C}$ ) it is affected by the length of prepolymer molecular during curing, whatever the degree of crosslinking. (Edited author abstract) 16 refs.

**081909 CHARACTERIZATION AND SPECTRO-ELECTROCHEMICAL STUDIES OF SOLUBLE POLYMERIZED 3-METHOXYTHIOPHENE.** 3-Methoxythiophene was polymerized anodically on glassy carbon or carbon felt electrodes. The resulting polymer was reduced cathodically and then isolated as a red solid, soluble in a variety of organic solvents. Following purification, the product was characterized by  $^1\text{H}$  and  $^{13}\text{C}$  NMR, UV-VIS, IR, HPLC and gel-permeation chromatography. These measurements indicated that the product is an oligomeric mixture  $n \approx 5-10$ , composed primarily of linearly linked 3-methoxythiophene units. The reduced polymer was coated onto various electrode materials and studied using cyclic voltammetry and spectroelectrochemistry. Details of electrolyte effects are reported. The reduced polymer absorbed light with  $\lambda_{\text{max}}$  480 nm. Upon oxidation over the range of 0.2-0.8 V (SCE) it was converted to an oxidized film which had a broad band with  $\lambda_{\text{max}}$  635 nm extending into the near-IR region. The  $A_{635}$  increased linearly with the charge passed, eventually leading to films that had about 10-20 cationic charges/100 monomer units. The electrochemical and optical behavior of this soluble oligomeric mixture is quite similar to insoluble polythiophenes. (Author abstract) 16 refs.

**081910 BOUNDARY EFFECTS ON POLYMER DYNAMICS IN DILUTE SOLUTIONS.** The motion of chainlike bead-spring molecules in dilute solution under the influence of a neighboring boundary is studied. Without restricting the problem to a specific flow regime or confining geometry, the Fokker-Planck equation for the polymer distribution in configuration space is treated in a mathematically formal way. A diffusion equation for the polymer concentration can be obtained if the hydrodynamic interactions among the solid surfaces are neglected. The work is useful in the fundamental treatment for the restricted transport of flexible macromolecules in dilute solution. (Edited author abstract) 23 refs.

**081911 HIGHLY ASYMMETRIC-SELECTIVE AND STEREoselective POLYMERIZATION OF (RS)- $\alpha$ -METHYLBENZYL METHACRYLATE WITH CYCLOHEXYL-MAGNESIUM BROMIDE-AXIALLY DISSYMMETRIC 2,2'-DIAMINO-6,6'-DIMETHYLBIPHENYL SYSTEM.** Enantiomer-selective polymerization of (RS)- $\alpha$ -methylbenzyl methacrylate [(RS)-MBMA] was investigated in toluene at  $-30^{\circ}\text{C}$ . Reaction products between cyclohexylmagnesium bro-

mide (cHexMgBr) and axially dissymmetric 2,2'-diamino-6,6'-dimethylbiphenyl (AMB) in the mole ratio of 1.5:1 were used as a chiral initiating system. The polymer produced contained a biphenyl group from the catalyst fragment. In the copolymerizations between (RS)-MBMA and achiral methacrylates, the catalyst also showed high selectivity toward (RS)-MBMA. Each of the copolymers from methacrylates of methyl, benzyl, and diphenylmethyl alcohols was coisotactic, and the enantiomer selections were consistent with that observed for the homopolymerization. On the other hand, both the isotacticity of copolymer and the selection greatly decreased in the copolymerization with  $\alpha$ -dimethylbenzyl methacrylate which has no hydrogen at the  $\alpha$ -carbon of the ester group. **081913 POLY(PHENYLENVINYLEN); ENTWICKLUNG EINES ELEKTROAKTIVEN POLYMER-MATERIALS VOM UNSCHMELZBAREN PULVER ZUM TRANSPARENTEN FILM.** [Poly(phenylenevinylene): Development of an Electroactive Polymeric Material from Unmeltable Powder to Transparent Film]. The development of PPV systems has moved from intractable powders to flexible films. This opens new uses as thin film insulation material, as photoconductive electrophotographic recording material, and as novel electrochemical electrode material for polymer batteries. Tractable films were readily achieved either by transformation of a soluble precursor polymer or by introduction of solubilizing phenyl substituents. Contrary to widespread expectations PPV is not a metal-like conductor, but rather a broad-band gap photoconductor ( $E_g=2.4$  eV). However, it can be made highly conducting upon appropriate chemical or electrochemical treatment, thus forming several salt-like redox stages. (Edited author abstract) In German. 106 refs.

**081915 PREDICTION OF POLYMER-MELT RHEOLOGY FROM STRESS-RELAXATION MEASUREMENTS.** The ability of three viscoelastic theories to model the rheological behavior of cis-polyisoprene has been investigated. The material functions in the theories were determined from stress-relaxation measurements. The response of the polymer to ramp loading and unloading, and to several types of double-step deformation were measured, and the observations compared with

predictions calculated from the theories. The theory that was the simplest to use gave predictions that were the closest to the observations. (Edited author abstract) 22 refs.

**081916 BIDIRECTIONAL CHARGE TRANSFER IN REPEATED CONTACTS TO POLYMERS.** The contact charging of polymers by metals is thought to be a consequence of electron transfer; the direction of transfer appears to be influenced by the relative position of the fermi level of the metal and some energy level characteristics of the polymer. What determines the amount of charge transfer is not definitely known at present. In this note we report experiments which show that charge accumulation is not always monotonic: although the magnitude of the charge always increases on average, the charge transfer in any particular contact can be of either sign. We think this effect is important because it puts strong constraints on possible mechanisms of contact electrification. 15 refs.

**081917 SYNTHESIS AND CHARACTERIZATION OF A WATER-SOLUBLE AFFINITY POLYMER FOR TRYPSIN PURIFICATION.** A specific ligand bound polymer has been synthesized for the purpose of purification and stabilization of trypsin, an easily autolytic enzyme. The affinity polymer was formed by copolymerizing N-acryloyl-m-aminobenzamide, a strong trypsin inhibitor, and acrylamide in the absence of oxygen. Kinetic studies on the trypsin inhibition revealed that there was a strong binding between this enzyme and the polymer and the mechanism was of a competitive manner with an inhibition constant of  $0.6 \times 10^{-3}$  M. Such an affinity polymer was also very effective in preventing trypsin from auto-digestion at  $4^{\circ}\text{C}$ . Based on this finding and the principle of cross flow filtration, a new process has been developed for purification of trypsin from a solution containing chymotrypsin. The experimental data indicated that trypsin was bound to the polymer ( $\text{MW} > 10^5$ ) and remained in the retentate while unbound chymotrypsin was collected in the filtrate. This purification process has a capability of recovering 98% pure trypsin at 90% yield. (Author abstract) 11 refs.

**081918 MULTINUCLEAR MACROMOLECULAR METAL COMPLEXES: III. PREPARATION AND PROPERTIES OF POLY(VINYLAMINE)COPPER-(II) COMPLEX COORDINATELY BONDED WITH HEXACYANOFERRATE(II).** A new multinuclear macromolecular metal complex, poly(vinylamine)copper(II) complex coordinately bonded with hexacyanoferrate(I), has been prepared by mixing aqueous solutions of poly(vinylamine)copper(II) and potassium hexacyanoferrate(II) in order to investigate the effects of macromolecularization of a mixed metal complex. The interactions between metals in different complex moieties of poly(vinylamine)copper(II) and hexacyanoferrate(II) were studied spectroscopically. A mixed metal polymer complex which has Fe(II), Cu(II), and vinylamine of the poly(vinylamine) repeating unit in the ratio of 1:1:20 has been prepared. The spectral data suggest that this mixed metal polymer complex has a cyanide bridged structure and interactions between metals of different complex moieties through the cyanide bridges. (Edited author abstract) 12 refs.

**081919 HELICAL POLY(AMINO ACID) HAVING CARBAZOLE SIDE CHAINS: A CANDIDATE FOR A PHOTOELECTRIC LIQUID CRYSTAL. 3. A CONFORMATIONAL STUDY.** The conformation of a carbazole-substituted poly( $\alpha$ -amino acid), poly(N<sup>ε</sup>-(carbazolyl-carbonyl)-L-lysine) (PKL), has been studied in solid films and solutions by Fourier transform infrared spectroscopy. In all samples investigated the main chain assumes the  $\alpha$ -helical conformation. The side chains are strongly hydrogen bonded in the solid state, with approximately 20% unbound groups. A side-chain conformation is proposed, where the major part of the side chains are stacked in three stacks almost parallel to the molecular axis. The average stack length exceeds 10 units and can in principle be infinite. The carbazole groups in the stacks are efficiently locked-in conformationally in a structure which probably favors effective energy transfer and photoconduction. In solution the hydrogen bonding of the side chains is disrupted. (Author abstract) 43 refs.

**081920 EQUATIONS OF STATE FOR POLYMER LIQUIDS.** There are numerous equations of state in the literature which propose to describe polymer liquids. We examine the assumptions on which these various equations are based and compare them using PVT data for a wide range of polymer data. We demonstrate that those theories based on the Lennard-Jones and Devonshire cell model best describe the polymer liquid state. The simple cell model provides a tractable and analytically simple equation of state for the analysis of polymer liquids. (Author abstract) 17 refs.

Dee, G.T. (DuPont, Wilmington, DE, USA); Walsh, D.J. *Macromolecules* v 21 n 3 Mar 1988 p 811-815.

**081921 MODIFIED CELL MODEL EQUATION OF STATE FOR POLYMER LIQUIDS.** The authors modify the cell model equation of state and demonstrate how such an equation can provide a better description of polymer liquids. This equation provides the analytical simplicity of the P.J. Flory, R.A. Orwoll, and A. Vrij (FOV)<sup>2</sup> equation of state and an accuracy, which for most polymer liquids, exceeds the Simha-Somcynsky equation. They show that a modification of the free volume term in the free energy for the cell model of polymer liquids results in these enhanced properties. 6 refs.

**081923 SEGMENT DISTRIBUTION ABOUT THE CENTER-OF-MASS IN AN ISOLATED POLYMER COIL. A RENORMALIZATION GROUP STUDY.** We analyse the segment density distribution about the center of mass in an isolated self-interacting polymer chain. We find that the center-of-mass operator is renormalizable without introducing new renormalization factors. The segment density distribution is calculated to one loop order. The interaction reduces the density in the center of the chain. This effect, which was to be expected, is due to a somewhat surprising mechanism: the interaction suppresses fluctuations of individual segments away from their average position. (Author abstract) 10 refs.

**081925 POLY ETHYLENE GLYCOL DERIVATIVES AS PHASE TRANSFER CATALYSTS AND SOLVENTS FOR ORGANIC REACTIONS.** The use of polyethers, specifically poly(ethylene glycol)s (PEG), as reagents in organic synthesis can be arbitrarily divided into three areas: 1) phase transfer catalysts, 2) supported catalysts, and 3) reaction solvents. The authors examine each of these areas in detail. It is shown that PEG's are excellent catalysts and solvents for a wide variety of organic reactions. In fact, contrary to conventional wisdom, they may be used in most applications where crown ethers are currently used. While it is true that the reactivity of PEG's is often less than that of crown ethers, this may be compensated for by simply raising the level of PEG concentration. PEG's appear to offer a number of very substantial advantages over the more commonly used crown ethers, e.g., lower cost and minimal, if any, toxicity. In general, when used as PTC's (Phase Transfer Catalysts) it has been shown that there is usually a minimum molecular weight for catalytic activity, > 200 g/mol. 53 Refs.

## Absorption

**081926 APPROACH FOR ESTIMATING THE PERMEATION OF PHOSPHONOFUORIDATES INTO A HIGH POLYMER MATRIX PART 1. DEVELOPMENT OF THE APPROACH.** An approach has been developed to estimate the solubility and diffusivity of toxic phosphonofluoridates in high-molecular weight polymeric matrices based upon experimentation with nontoxic simulants. This approach is based on Gee's relation for estimating solubility (equilibrium swelling) from knowledge of the solubility parameters for the polymer and the simulant liquids concerned and on Van Krevelen's relation between diffusivity and activation energy of diffusion. The latter is interpolated from a standard plot of activation energy of diffusion against penetrant molar volume. Equilibrium swelling values and diffusivities for toxic alkyl phosphonofluoridates in styrene-butadiene rubber (SBR) and low density polyethylene (LDPE) were estimated from results of swelling measurements. (Edited author abstract) 9 refs.

**081927 POLYMER ADSORPTION NEAR THE SURFACE OF A POLYMER SOLUTION: A UNIVERSAL BEHAVIOUR.** A universal property of good solutions of long polymers near an attractive surface is studied under the assumption that there is saturation on the surface and that the monomer concentration vanishes at infinity. The generalization of an argument given by P.G. de Gennes indicates that, at a distance  $x$  from the surface, the kuhnian concentration (monomer concentration)  $C_k(x) = A(d)x^{-d+1/4}$  where  $d$  is the space dimension and  $\nu$  the critical size exponent. It is shown that a mean field theory is valid for small values of  $\epsilon = 4 -$

$d$  and that it leads to the result  $A(4 - \epsilon) = 2/\pi^2\epsilon$ , for  $0 < \epsilon \ll 1$ . (Author abstract) 3 refs.

**081933 ADSORPTION OF A THETA POLYMER: COMPETITION BETWEEN MEAN-FIELD AND MULTICRITICAL BEHAVIOUR.** We analyze the behavior of a 3d theta polymer in the presence of an attracting wall. We find that the multicritical crossover exponent at the adsorption temperature  $T_a$  is the mean-field  $\phi = 1 - \nu_{MF} = 1/2$ . However, one only finds a consistent estimate of  $T_a$  if logarithmic corrections are taken into account. This is the first example of numerical data of walks where logarithmic corrections clearly dominant all other possible corrections to scaling. The monomer density near the surface is reduced compared to the mean-field and good-solvent case. (Author abstract) 33 refs.

**081935 INTERFACIAL BEHAVIOUR OF BINARY POLYMER MIXTURES II. COMPETITIVE POLYMER ADSORPTION AND ITS EFFECT ON THE STABILITY OF COLLOIDAL DISPERSIONS.** This paper describes the adsorption of methylcellulose (MC), polyvinyl alcohol (PVA) and polyvinyl pyrrolidone (PVP) and of their binary mixtures on arsenic trisulphide sol and polystyrene latex, and the effect of these polymers and polymer mixtures on the stability of the dispersions. The conditions for binary polymer mixtures resulting in a synergistic effect and the relation of this phenomenon to competitive adsorption of the polymers were studied. Upon simultaneous adsorption from binary mixtures, the order of preferential adsorption for the polymers is as follows: PVP > MC > PVA on the arsenic trisulphide

sol, and MC > PVP > PVA on the polystyrene latex. At high surface coverage, the weakly adsorbed polymers can be displaced from either interface by the preferentially adsorbed polymers. The effectiveness of the polymer mixtures, both as flocculants and stabilizers, closely correlates with the order of preferential adsorption for the polymers. Synergism in the flocculating effect of MC-PVP mixtures with components of different molecular mass on arsenic trisulphide sol was found. At the onset of the stabilizing region, some increase in the effectiveness of MC-PVP and PVA-PVP mixtures on arsenic trisulphide sol was also observed. These phenomena are attributed to irregularly extended adsorption layers formed by the competitive adsorption of the polymers. (Edited author abstract) 13 refs.

**081936 POLYMER ADSORPTION: CONCENTRATION EFFECTS.** We consider the various adsorption regimes of flexible chains in a good solvent when the bulk concentration is changed. As the latter is increased, first we find a very dilute bulk regime where the surface coverage increases fast. This is followed by a plateau with much slower increase for  $\Gamma$ , the bulk solution being still dilute. In the bulk semi-dilute regime, we consider the adsorption of blobs. For high bulk volume fraction  $\phi_b > \delta^4/3$ , where  $\delta$  is the dimensionless excess energy per monomer on the surface, the blobs are not adsorbed. The interfacial tension is calculated in the different regimes. Our approach closely follows the scaling theory of de Gennes and Pincus. (Author abstract) 29 refs.

**081937 CONTRIBUTION OF ADSORBED POLYMERS TO THE STABILITY OF COLLOIDAL SYSTEMS.** A review is presented of contemporary ideas concerning adsorption of polymers and polyelectrolytes and their effect on colloid interaction. A discussion is also presented of the following topics: the effect of important parameters is well understood, including molecular mass, adsorption energy, solvent quality, polydispersity, and, in the case of polyelectrolytes, the effect of charge and concentration of the electrolyte. (Edited author abstract) 10 refs.

**081938 CHEMISORPTION GEOMETRY OF POLY-3-METHYLTHIOPHENE ELECTROCHEMICALLY DEPOSITED ON Pt AS OBSERVED BY NEXAFS.** NEXAFS measurements have been employed to investigate the Pt-poly-3-methylthiophene (PMeT) interface. The C 1s and S 2p edge characteristics reveal that the polymeric chains are well ordered on the metallic surface even for thicknesses up to 50 Å. In its undoped semiconducting state, the polymeric layers lie flat on the Pt with a strong interaction between electron states of the metal and the antibonding  $\Pi^*$  band of the PMeT. When PMeT is electrochemically doped to its conducting state, the NEXAFS spectra exhibit changes as a function of thickness. The first layer lies essentially flat on Pt, while the other ones are randomly oriented, according to the intercalation of anions during the oxidation process. The ordering and the homogeneity of the first layers strongly depend on the electric field applied at the Pt-electrolytic medium interface during the electrochemical synthesis. (Author abstract) 16 refs.

**081939 ELECTROPHORETIC STUDY OF POLYMER ADSORPTION: DEXTRAN, POLYETHYLENE OXIDE AND POLYVINYL ALCOHOL ON SILVER IODIDE.** The adsorption of polyvinyl alcohol (PVA), dextran (DEX), and polyethylene oxide (PEO) on

silver iodide has been measured together with the electrophoretic mobilities of the polymer-covered particles and the surface charge. The combined information from these three sources allows a detailed analysis of the composition of the polymeric adsorbate and the electrical double layer to be made. Polydispersity is accounted for and a special method has been developed to cover particles with a thick polymer layer. Electrophoretic layer thicknesses  $\delta_E$  are established under conditions where they are identical to the hydrodynamic thicknesses. For a given polymer,  $\delta_E$  depends only on the amount adsorbed and not on the molecular weight (molecular weight congruency). The solvent quality for the three polymers is reflected in  $\delta_E$  and in the extent to which train segments displace ions from the Stern layer. (Author abstract) 36 refs.

**081940 ADSORPTION OF PARTIALLY HYDROLYZED POLYACRYLAMIDES ON TITANIUM DIOXIDE.** The adsorption of partially hydrolyzed (0, 4, 16%) polyacrylamides on titanium dioxide in an aqueous medium was studied to analyze the influence of pH, ionic strength, and the presence of  $\text{Ca}^{2+}$  complexing ions. Experimental results cannot be explained solely by considering the variation of the polymer's and surface's charge densities. An important parameter concerning the polymer's affinity for the surface could be the variation of its solubility in the medium. (Author abstract) 19 refs.

**081941 SURFACE-ENHANCED RAMAN SPECTROSCOPY OF POLY(2-VINYLPYRIDINE) ADSORBED ON SILVER ELECTRODE SURFACES.** Surface-enhanced Raman scattering (SERS) of partially protonated poly(2-vinylpyridine) (P2VPy) adsorbed onto an electrochemically roughened silver electrode is reported as a function of applied potential. The species on the electrode surface is predominantly pyridinium ion when the electrode potential is positive of the point of zero charge ( $E_z$ ) and predominantly neutral pyridine near  $E_z$ . Orientation effects involving the polymer chain are visible in the fingerprint region of these spectra. The species vs potential dependence is different for the polymer compared with low molecular weight probe molecules of pyridine and 2-methylpyridine. The presence of the polymer substantially improves the stability of the active sites responsible for SERS activity to cathodic excursions to  $E_z$  in chloride electrolyte. The differences observed with the polymer are explained on the basis of its lower solubility and the 'anchoring' of positive charges within the double-layer region. (Author abstract) 42 refs.

**081943 POLYACRYLAMIDE Na-KAOLINITE INTERACTIONS: EFFECT OF ELECTROLYTE CONCENTRATION ON POLYMER ADSORPTION.** The variation in polyacrylamide adsorption on Na-kaolinite as a function of electrolyte concentration of the clay suspension, was determined under three pH conditions, where the clays display varying charge characteristics. Interpre-

tation of the results is based on two arguments: non-charged polyacrylamide adsorption is restricted to the edge faces of the colloidal platelets and hydrogen bonding between the amide groups of the polymer and the 'isolated' hydroxyl sites of these faces is the mode of surface attachment. At constant pH, when Na-kaolinite bears charged surface groups, the polymer adsorption, which is related to the density of the anchoring sites, parallels the state of ionization of the edge surface. (Edited author abstract) 36 refs.

**081944 SHORT TERM KINETICS OF POLYMER ADSORPTION ON GLASS SUBSTRATE.** Short term kinetics (1 to 60 s) of polymer adsorption on glass and the variation of the adsorption density along the surface have been studied using a new technique. This method also gives information on how the polymer is distributed spatially along the interface. The effect of polymer concentration and chemical pretreatment of the substrate with an inorganic on polymer adsorption is discussed. It appears that polymer adsorption does not take place uniformly and linearly with time. Initiation of polymer adsorption by some surface controlled factors appears to be necessary before it is followed by a rapid polymer uptake. (Author abstract) 1 ref.

**081945 SELF-CONSISTENT FIELD MODEL OF POLYMER ADSORPTION: GENERALIZED FORMULATION AND GROUND-STATE SOLUTION.** We formulate a general self-consistent field model of polymer adsorption and consider the case of nonionic homopolymer adsorption on a single, planar surface. Our approach is closely related to those of S.F. Edwards, K.F. Freed, and P. de Gennes in that we obtain a diffusion equation for the configuration probability of an idealized chain of polymer segments. We solve the general field equation through an eigenfunction expansion, keeping only the first, or ground state, function in the expansion. Comparison with experimental data and the results of the Scheutjens-Fleer lattice model demonstrate that the solution precludes the prediction of long, dangling tail configurations that influence many of the interactions of the adsorbed layer. (Edited author abstract) 41 refs.

**081946 HYDRODYNAMIC THICKNESS OF ADSORBED POLYMERS IN STEADY SHEAR FLOW.** The effective hydrodynamic thickness (EHT) of adsorbed polystyrene in toluene and cyclohexane and poly(acrylamide) in aqueous NaCl solvent, both at the adsorption plateau, was determined in a steady laminar shear flow in an array of fused glass capillaries. Effective hydrodynamic thicknesses were determined for a shear rate range of 170-800 s<sup>-1</sup>, with an EHT resolution of about ±50 Å. The EHT for polystyrene in toluene, and for poly(acrylamide) in a 1200 ppm aqueous NaCl solvent, was found to decrease from the zero shear EHT values with increasing shear rate. The zero shear limit of the EHT in a Θ solvent (cyclohexane at 34.8°C) was found to be lower than in a good solvent (toluene). This work is pertinent to ultrafiltration, wastewater treatment, and enhanced oil recovery. (Edited author abstract) 41 refs.

**081948 REACTIONS WITH COMPETITION IN THE THREE-COMPONENT POLYMER SYSTEM AEROSIL SURFACE-COPOLYMER OF STYRENE AND MALEIC ACID-POLYOXYETHYLENE.** The three-component system an aerosil silica-copolymer of styrene with maleic acid (CSMA)-polyoxyethylene (POE) has been studied by potentiometric titration, IR spectroscopy and viscometry. The reaction of macromolecular substitution occurring in solution on making CSMA with POE adsorbed on SiO<sub>2</sub> stops at the stage of formation of the POE CSMA polycomplex on the surface of the aggregated aerosil; the amount of CSMA in the mixed 'complex' depends on M<sub>POE</sub>. On introducing POE into a system of competing and interacting polyacids SiO<sub>2</sub> + CSMA it reacts not with the 'rigid' surface of the aggregated SiO<sub>2</sub> particles but with the flexible CSMA chains which is due to the greater gain in energy on formation of the polycomplex as compared with adsorption of the macromolecular on the surface. (Author abstract) 17 refs.

**081949 DYNAMICS OF ADSORBED POLYMERS. 1. THICKNESS RELAXATION OF POLY(VINYL-PYRROLIDONE) ON GLASS.** The authors present kinetic data that give a rather direct insight into the time scale of rearrangement processes occurring inside an adsorbed polymer layer. In particular, they were able to measure the hydrodynamic thickness of a freshly deposited adsorption layer as a function of time, and found it to decrease over a time of the order of minutes. The authors present data for this relaxation process, which show that it is not simply exponential and that it strongly depends on the thickness increment prior to relaxation. They also present data on the relaxed thickness as a function of the number of deposition steps, polymer concentration, and molecular weight. The results can be qualitatively understood in terms of a simple two-stage adsorption. (Edited author abstract) 18 refs.

**081950 FLUORESCENCE STUDIES OF POLYMER ADSORPTION. 1. REARRANGEMENT AND DISPLACEMENT OF PYRENE-TERMINATED POLY(ETHYLENE GLYCOL) ON COLLOIDAL SILICA PARTICLES.** Adsorption of pyrene end-labeled poly(ethylene glycols) (Py-PEG-Py) on colloidal silica particles and their subsequent rearrangement and/or displacement by the addition of unlabeled PEG are studied in water by using photostationary fluorescence and time-resolved fluorescence decay. The tagged polymers we use in this study have molecular weights 4250 and 8650 based on the PEG backbone. The molecular weight of the displacing polymer (PEG) ranges from 1470 to 22000. Experimental conditions for the adsorption of Py-PEG-Py are chosen to ensure that a negligible amount of Py-PEG-Py exists in free solution. The measurement of excitation spectra and time-resolved fluorescence decays for both monomer and excimer emission provides insight into the state of the Py-PEG-Py when adsorbed on a silica surface. (Edited author abstract) 36 Refs.

**081951 INVESTIGATION OF THE ADSORPTION CONFIGURATION OF POLY(ETHYLENE OXIDE)**

**AND ITS COPOLYMERS WITH POLY(PROPYLENE OXIDE) ON MODEL POLYSTYRENE LATEX DISPERSIONS.** Theoretical prediction of the performance of adsorbed polymeric dispersion stabilizers requires information on the configuration of polymers at the solid/liquid interface. Parameters describing polymer adsorption configuration on aqueous polystyrene latices are evaluated for representative linear homopolymers, block copolymers, and random copolymers of poly(ethylene oxide) and poly(propylene oxide). Effective hydrodynamic adsorption layer thicknesses, determined with photon correlation spectroscopy, are reported for the different polymer systems as a function of molar mass, concentration, and time from initial mixing. Specific adsorption isotherms are also determined. The data suggest that the polymers adsorb in the extended configuration, as loops and/or tails. (Author abstract) 37 Refs.

**081952 ADSORPTION/DESORPTION OF A PEO-RICH COMB-LIKE POLYMER AT A SILICA/AQUEOUS SOLUTION INTERFACE.** The adsorption isotherm of a polymethacrylate of monoethoxy-poly(ethylene glycol) from aqueous solutions on silica was found to be of high affinity type. Homogeneous and heterogeneous [with linear poly(ethylene oxide), PEO] exchange between adsorbed and dissolved molecules was performed with radiolabeled polymers: results suggest the anchoring of the polymer by the backbone, the tails of PEO protruding into the bulk solution. Pretreatment of silica with such a polymer reduces the adsorption of fibrinogen to 5 percent of the value observed with bare silica. (Author abstract) 28 Refs.

**081953 COMPETITIVE AND DISPLACEMENT ADSORPTION OF POLYELECTROLYTE AND WATER-SOLUBLE NONIONIC POLYMER AT THE SILICA SURFACE.** Individual, competitive, and displacement adsorption of poly(ethylene oxide) (PEO) with a narrow molecular weight distribution and poly(4-vinyl-N-n-propylpyridinium bromide) (PVPP) with complete quaternization onto a nonporous silica (Aerosil 130) from an aqueous KBr solution, pH 4, at 25°C was studied as a function of KBr concentration and molecular weight of PEO. In individual adsorption, adsorbed amount of both PEO and PVPP increases with increasing KBr concentration due to a decrease in excluded volume effects of polymer chains. In competitive adsorption, PEO adsorbs preferentially over PVPP due to the strong hydrogen bonds between PEO and silanol groups. In displacement adsorption PVPP molecules are desorbed from the silica surface by addition of PEO molecules. Both competitive adsorption and exchangeability slightly increase with increasing molecular weight of PEO. (Author abstract) 29 Refs.

**081954 POLYMERS IN COLLOID SYSTEMS: ADSORPTION, STABILITY AND FLOW, PROCEEDINGS OF AN INTERNATIONAL CONFERENCE.** This conference proceedings contains 29 papers. All papers are indexed and abstracted separately. Topics covered include: progress in polymer adsorption; random copolymer adsorption; block copolymer adsorption; hydrodynamic layer thicknesses; polymer desorption; adsorbed fibrinogen layer structural changes; ion exchange reactions during adsorption of cationic polyelectrolytes; forces between surfaces bearing polymer chains; forces between adsorbed layers; static and dynamic forces across polymer liquid films; flocculation of cellular suspensions by electrolytes; studying polymer interfacial dynamics; adhesive hard sphere colloidal dispersions; solvent in-

duced flocculation of polymer colloids; depletion flocculation of concentrated sterically stabilized polystyrene latex dispersions; use of concentration profiles in creaming emulsions; and a mean field theory for the rheology of phase-separated or flocculated dispersions. Technical and professional papers from this conference are indexed and abstracted with the conference code no. 11533 in the Ei Engineering Meetings (TM) database produced by Engineering Information, Inc.

**081955 THEORETICAL PROGRESS IN POLYMER ADSORPTION, STERIC STABILIZATION AND FLOCCULATION.** The range of validity of scaling and mean field models for polymers at interfaces is discussed. According to a recent analysis by D.W. Schaefer, mean field theories describe the properties of polymers in solution correctly over a wider range of concentration and solvency than does scaling. Only for flexible polymers in very good solvents at concentrations below a few percent are scaling methods preferred. In polymer adsorption, high segment densities occur and therefore mean field theories are more appropriate than scaling. The most detailed mean field theory for polymers at interfaces has been proposed by J.M.H.M. Scheutjens and G.J. Fleer. The distribution of segments as a function of ranking number and, consequently, end effects (tails) are taken fully into account. (Edited author abstract) 53 refs.

**081956 EXTENSIONS OF THE SELF-CONSISTENT FIELD THEORY OF POLYMER ADSORPTION: MATCHED ASYMPTOTIC SOLUTION DESCRIBING TAILS.** Near the surface, the polymer is grossly distorted from the ideal state due to the effect of adsorption; the characteristic length is the segment length, and the groundstate solution is roughly correct. Far from the surface, polymer configurations are more nearly random walks with a characteristic length given by the square root of the chain length (number of segments per polymer chain). Asymptotic matching yields a uniformly valid approximate solution for the end segment probability as just the sum of the groundstate solution and the error function. The simplicity of the solution allows calculation of analytical volume fraction profiles; furthermore, the contributions due to segments contained in trains, loops, tails, and free polymer can be identified. 5 refs.

**081957 HYDRODYNAMIC LAYER THICKNESSES OF VARIOUS ADSORBED POLYMERS ON PRECIPITATED SILICA AND POLYSTYRENE LATEX.** Hydrodynamic layer thicknesses of adsorbed polyethylene oxide (PEO), polyethylene oxide-polypropylene oxide-polyethylene oxide (PEO-PPO) block copolymers, and polyvinyl alcohols (PVA) of different molar mass and composition are determined by photon correlation spectrometry (PCS) and ultracentrifugation (UC). The adsorbents used are precipitated silica and polystyrene latex. The increase of the diffusion coefficient,  $D$ , of the bare silica particles with reduction of the electrostatic double layer is related to the existence of immobilized water near the charged interface. At high PEO adlayer thicknesses no influence of the extension of the double layer exists. (Edited author abstract) 26 refs.

**081958 SURFACE FORCE MEASUREMENTS FOR POLY-L-LYSINE: EFFECT OF IONIC STRENGTH.** The authors have carried out measurements, using the surface forces apparatus, for the interaction of poly-L-lysine (PLL) chains adsorbed on mica from electrolyte solution. The results agree well with earlier work by P.F. Luckham and J. Klein and form part of a more detailed study carried out for a range of molecular weights for this polyelectrolyte. In the highest electrolyte concentration, 0.1 mol dm<sup>-3</sup> KNO<sub>3</sub>, there is no background double-layer repulsion due to the electrolyte, and so any observed repulsion is entirely due to the polymer adsorbed on the mica surface. 5 refs.

**081959 POLYMER ADSORPTION AND FLOCCULATION IN SHEARED SUSPENSIONS.** Dynamic aspects of polymer adsorption and flocculation are considered and their relevance to the testing of polymeric flocculants is emphasised. In particular, the adsorption of polymer on particles can be slow compared to the flocculation rate in sheared suspensions, and this can lead to some uncertainties in the interpretation of results from continuous tests. Results using a newly-developed flocculation monitor are presented, with a variety of suspensions and polymers, which illustrate some of the important points. (Author abstract) 26 refs.

**081960 ELLIPSOMETRIC STUDY OF POLYMER MONOLAYERS SPREAD AT THE AIR-WATER INTERFACE. 1. THICKNESS OF MONOLAYERS.** In this paper the applicability of ellipsometry for investigating the behavior of polymer monolayers spread at the air-water interface is explored. Polymer monolayers used in this study are poly(ethylene oxide) (PEO), poly(tetrahydrofuran) (PTHF), poly(vinyl acetate) (PVAc), poly(methyl methacrylate) (PMMA), and poly( $\gamma$ -methyl-L-glutamate) (PMLG). Their interfacial properties are discussed as a function of surface concentration and surface pressure. Moreover, the calculation of the thickness and refractive index of the polymer monolayers is performed and the conformation of polymer chains at the air-water interface is also discussed in terms of the hydrophilicity or hydrophobicity of polymers. 25 refs.

**081961 ELLIPSOMETRIC STUDY OF POLYMER MONOLAYERS SPREAD AT THE AIR-WATER INTERFACE. 2. ADSORBED AMOUNT OF POLYMERS.** Ellipsometry has been used to calculate the refractive index and thickness of polymer monolayers of poly(ethylene oxide) (PEO), poly(tetrahydrofuran) (PTHF), poly(vinyl acetate) (PVAc), and poly(methyl methacrylate) (PMMA) spread at the air-water interface as a function of surface concentration and surface pressure. From the refractive index and thickness of the adsorbed monolayers we attempted to calculate the adsorbed amounts of polymers in the monolayers in terms of the Lorentz-Lorenz relation for an ideal mixed layer of polymer and surrounding media as a function of the refractive index  $n_s$  of the surrounding media. The adsorbed amount of polymer so calculated for  $n_s = 1$  corresponding to air is much larger than that for  $n_s = 1.334$  corresponding to water. The latter adsorbed amount is in agreement with the real spread amount of polymer in the entire surface concentration range irrespective of polymer species. This agreement indicates that the poly-

mer chains are surrounded by water molecules by taking an extended conformation normal to the water surface for PTHF and PVAc and a flattened one for PEO and PMMA at higher surface concentration. (Author abstract) 17 refs.

**081962 MULTIORDERING PARAMETER MODELS OF VOLUME AND ENTHALPY RECOVERY GENERALIZED TO TREAT PHYSICAL AGING; A QUANTITATIVE INVESTIGATION.** Multiordering parameter models have been quite successful in rationalizing volume and enthalpy behavior of glasses subjected to various thermal histories in the glass transition range and even at lower temperatures. In the past we suggested a generalization of such models to encompass what is now termed physical aging, i.e., recovery as monitored by mechanical experiments such as creep and stress relaxation. Our initial investigation indicated qualitative agreement between the generalized model and experimental behavior. We have now more completely investigated this area and found a convenient approximation through which behavior can be calculated in most situations without using a distribution of mechanical relaxation or retardation times. Using this technique, we find that essentially quantitative agreement between this model and experimental results is possible only when a very sharp distribution of volumetric recovery times, like that of a single ordering parameter model, is used. (Edited author abstract) 22 refs.

**081963 ASPECTS OF THE THERMAL AGEING OF POLYDODECANAMIDE IN A HUMID ATMOSPHERE.** Wide and small angle X-ray analysis, IR spectroscopy, viscometry and electron microscopy for chemical analysis have been employed to study the changes in the physical and chemical structure of isotropic and oriented polydodecanamide during moist heat aging. It is shown that the degradative processes occurring in the volume and on the surface of the polymer are fundamentally different. Uniaxial orientation of polydodecanamide films enhances the stability of the polymer to the action of temperature and moisture. (Author abstract) 16 refs.

**081964 ACCELERATED AGEING OF POLYMERS UNDER THE EFFECT OF SUPERHIGH FREQUENCY RADIATION.** The results are presented of investigations into accelerated ageing of silicon-organic materials under the effect of coherent superhigh frequency radiation in the centimeter wavelength range. The experimental procedure is described. The phenomena detected are analyzed and the probable thermoelectric mechanism of accelerated ageing of silicon-organic polymers (oligomers) in the superhigh frequency field is explained. It is proposed to use decelerating systems for ageing only the surface layers of the polymer. A method of calculating the surface life of the polymer in the component on the basis of the results of superhigh frequency irradiation is proposed. (Author abstract) 28 refs.

**081966 MECHANISM OF AGEING IN IRRADIATED POLYMERS.** Samples of ultra-high molecular weight polyethylene (UHMWPE) and nylon 66, of grades suitable for use in medical prostheses, were subjected to irradiation using a  $^{60}\text{Co}$  source. The effects of a 10 Mrad dose on percentage crystallinity, tensile behavior and dynamic mechanical response were established 3 days after irradiation, and irradiated samples were then retested at intervals over a one year period. Crystallinity in UHMWPE was found to increase progressively during this period with consequent changes in mechanical behavior. It is proposed that the observed ageing process arises from the breakdown of metastable groups in the polymer, which are formed from the breakdown of metastable groups in the polymer, which are formed on irradiation with consequent release of long inter-lamella tie chains. This removes an inhibition to crystal perfection processes, which can occur at room temperature in polyethylene. It is proposed that the metastable species introduced on irradiation is peroxy or hydroperoxy and that this decomposes on ageing to a carbonyl group, which concurrent chain scission. (Edited author abstract). 12 Refs.

**081967 VOLUME RELAXATION AND SECONDARY TRANSITIONS IN AMORPHOUS POLYMERS.** For a number of polymers, the volume relaxation occurring after quenching from above to below glass transition temperature,  $T_g$  has been studied by length dilatometry. By varying the test temperature between  $-180^\circ\text{C}$  and  $T_g$ , the temperature regions of several secondary transitions were covered. Volume relaxation rate was found to show similar (secondary) peaks as the mechanical damping. The theoretical implications of these findings are discussed. (Edited author abstract) 23 refs.

Struik, L.C.E. (TNO, Delft, Neth). *Polymer* v 28 n 11 Oct 1987 p 1869-1875.

**081968 CONTRIBUTION OF A DIFFUSIONAL MECHANISM TO THE RELAXATION OF FREE VOLUME IN AMORPHOUS POLYMERS.** The ratio of local and diffusional mechanism of relaxation of excess free volume in amorphous polymers is discussed. On the basis of ideas on the finite lifetime of holes, a model is formulated for the relaxation of volume in accordance with a diffusional mechanism. The diffusion mechanism can be important for the volume relaxation of specimens of linear dimensions of the same order as the  $(D\tau)^{0.5}$  value, where  $\tau$  is the lifetime of a hole, and  $D$  is the effective diffusion coefficient, i.e. the contribution of the diffusional mechanism to the mechanism of relaxation depends on the specimen size. (Author abstract) 25 refs.

**081969 DENSIFICATION AND ORIENTATION ON POLING IN COPOLY(VINYLIDENE CYA-**

**NIDE/VINYL ACETATE) WITH THE AID OF  $^{13}\text{C}$  CP/MAS NMR SPECTROSCOPY.** Since high piezoelectricity was observed in copoly(vinylidene cyanide/vinyl acetate) [P(VDCN/VAc)], amorphous polymers have received attention as new piezoelectric materials. Recently, information concerning the molecular structure of amorphous polymers in the solid state has been successfully obtained by using cross-polarization (CP) magic-angle spinning (MAS) NMR experiments with high-power dipolar decoupling (DD). Previously, we reported the molecular dynamics of P(VDCN/VAc) and P(VDCN/MMA), (MMA = methyl methacrylate) by  $^{13}\text{C}$  CP/MAS NMR spectroscopy, where the nonequivalence of piezoelectricity in these two copolymers is found to originate from the difference of the segmental mobilities. In this communication, we report the  $^{13}\text{C}$  CP/MAS spectra of powder, drawn, and poled P(VDCN/VAc) samples and discuss the effects of drawing and poling in terms of the proton spin-lattice relaxation times in the rotating frame and the linewidths of  $^{13}\text{C}$  CP/MAS NMR spectra. Also the poling effect is elucidated by DSC measurements. 16 refs.

**081970 ELECTRICAL CONDUCTIVITY OF SOME AMORPHOUS POLYMERS.** ac Conductivity of two acrylates, namely, polymethyl methacrylate (PMMA) and polyethyl methacrylate (PEMA) have been evaluated using dielectric data in the frequency range of  $10^2$ - $10^5$  Hz and the temperature regions of 311-337.6 K and 89-114 K. A relation of the type  $\sigma = \epsilon_0 \epsilon'' \omega$  has been used for the purpose. A correlation of  $\sigma$  with the frequency of measurement has been studied. This seems to obey a relation of the type  $\sigma = A(\omega)^S$  where  $S$  lies between 0.86 to 1.0. This is in agreement with the results obtained by earlier workers on amorphous solids. An estimate of activation energy has also been made in the lower temperature region. In the higher temperature region where the cooperative phenomena occur, the variation of  $\sigma$  has been found to be nonlinear. (Author abstract) 17 refs.

**081971 ELECTRONIC TRANSPORT IN AMORPHOUS SILICON BACKBONE POLYMERS.** Measurements of hole transport in polysilylenes have been carried out over an extended range of temperature and field. This extended data facilitates detailed comparison to extensively characterized glassy carbon backbone polymers like poly(N-vinylcarbazole)(PVK). Hole transport data in polymethylphenylsilylene (PMPS) serves as a model and has been analyzed in both a modified Arrhenius framework and in terms of a picture of hopping in a Gaussian distribution of states broadened by disorder. The principal conclusion is that respective transport properties observed in PMPS and PVK are surprisingly similar despite the following key difference: hole or hole polaron transport in PVK does not involve states derived from the carbon backbone but rather direct hopping among pendant carbazole sidegroups which can be thought of as isolated small molecules (chromophores). Other results indicate that in polysilylenes generally, transport states probably associated with the chain backbone still remain relatively localized. (Edited author abstract) 14 refs.

**081972 EFFECT OF COMBINED PRESSURE AND TEMPERATURE CHANGES ON STRUCTURAL RECOVERY OF GLASS-FORMING MATERIALS. I. EXTENSION OF THE KAHR MODEL.** There have been several basically equivalent phenomenological approaches to the modeling of the behavior of polymeric and inorganic glass-forming materials. This paper presents an extension of the KAHR model, put forward by Kovacs, Aklonis, Hutchinson, and Ramos. The KAHR model of

structural relaxation has been extended to include the effects of pressure upon the retardation times of glass-forming materials. The previously used methodology is applied with a continuous distribution of retardation times of the fractional exponential form. Several forms of the pressure dependence are examined. The combined temperature and pressure changes on structural recovery of glasses are addressed in this paper. (Edited author abstract) 23 refs.

**081973 TEMPERATURE DEPENDENCE OF RELAXATION PROCESSES IN AMORPHOUS POLYMERS.** Recently it was pointed out by Prof. D.J. Plazek that the various empirical expressions used in literature until today, to describe the temperature dependence of the relaxation processes in amorphous polymers above the glass transition temperature, failed to describe the experimental data correctly. The most widely used expression is the Vogel-Fulcher equation (V-F equation). The author used a new empirical equation used by M. Shablaikh and others to describe dielectric relaxation processes which is known in critical phase transition theory. The results of new computations taking into account the thermodynamic properties and effects on viscosity of the polymers are presented and discussed. 39 Refs.

**081974 ON THE NATURE OF THE FREE VOLUME IN AMORPHOUS POLYMERS.** In a previous publication it was shown that the free volume in amorphous polymers cannot consist of empty sites according to the quasilattice model. In this paper it is demonstrated why theories which are based on the assumptions of this model are nevertheless partly successful. It is even possible to calculate all three jumplike alterations in the second derivatives of Gibbs free energy at the glass transition in accordance with the experimental results. As far as we know, this is the first time that, in addition to the steplike changes in the thermal expansion coefficient  $\Delta\alpha$  and the specific heat  $\Delta c_p$ , the analogous change in the compressibility  $\Delta\kappa_{ch}$  can also be described correctly by a theory. The parameters for accommodation however reveal, that the quasilattice model does not apply. Consequently better-founded equations are derived, which despite their simplicity, give excellent agreement with the experimental data. (Edited author abstract). 26 Refs.

**081975 BRILLOUIN SCATTERING STUDIES OF STRUCTURAL RELAXATIONS IN POLY(PROPYLENE GLYCOL).** Structural relaxation processes in poly(propylene glycol) (PPG), molecular weight 10,000, have been examined at the high frequencies of Brillouin scattering. By combining the high-frequency results with reported photon correlation data, the relaxation time  $\tau$  is established over a wide timescale of  $1 \cdot 10^{-11}$  s. Over the whole range, the relaxation times can be described by a single equation. Single relaxation time theory does not fit the experimental results; the width is characterized by  $\beta = 0.4$  in a Williams-Watts distribution of relaxation times. The observed behavior is explained in terms of restricted local intrachain motions. (Edited author abstract) 17 refs.

**081977 RELATION BETWEEN EXCIMER FORMATION IN SMALL PROBES AND FREE-VOLUME THEORY IN POLYMER MELTS.** Intramolecular excimer formation of meso-2,4-di(N-carbazolyl)pentane dissolved in different elastomers has been investigated. The intramolecular conformational change required for the excimer sampling process is shown to be controlled by the segmental motions of the polymer matrix involved in the glass transition phenomenon. The results show that, at a fixed frequency of the probe motion, the fractional free volume as well as the free volume per atomic group vary from one polymer to another. (Author abstract) 12 refs.

**081981 POLYMER-POLYMER MISCIBILITY AND ENTHALPY RELAXATIONS.** Annealing of poly-

ymers below the glass transition temperature results in a decrease in enthalpy that is recovered during heating. The enthalpy recovery is visible as an endothermic peak in a differential scanning calorimetry (DSC) scan. The position of this peak depends on the thermal treatment given and on the structure of the material itself. Because different polymers behave differently, the phenomenon can be utilized to investigate polymer-polymer miscibility of polymers with similar  $T_g$  values. Therefore, by annealing the blends at the temperature of interest and subsequent sub- $T_g$  annealing, one can monitor phase behavior resulting from the initial treatment by inspection of the enthalpy recovery. **081983 MECHANISTIC ACTION OF PHENOLIC ANTIOXIDANTS IN POLYMERS - A REVIEW.** Hindered phenols are used as radical scavengers during fabrication, storage, processing and end-use of various polymers. Modern HMW antioxidants have very sophisticated molecular architectures, combining intrinsic chemical activity and the requirements of physical persistence. The mechanism of action has been discussed using the results of the elucidation of the chemical transformations which occur during the stabilisation process. Mechanisms responsible for co-operation phenomena, regenerative processes involved in homo- and heterosynergism, intramolecular co-operation in bifunctional phenolic antioxidants and co-operation pathways between hindered phenols and HALS are shown. Various catalytic species and some pigments are able to induce chemical transformation of hindered phenols and reduce their efficiency. (Author abstract) 48 refs.

**081984 SPECTROSCOPIC STUDY OF OXYGEN SORPTION AND DIFFUSION IN A MEMBRANE CONTAINING A COBALT PORPHYRIN COMPLEX.** The kinetics and equilibrium of molecular oxygen sorption in the membrane containing [α,α',α'',α'''-meso-tetrakis(o-pivalamidophenyl) porphyrinato]cobalt(II)-1-methylimidazole (CoPlm) complex which forms oxygen adduct rapidly and reversibly are studied spectroscopically. Oxygen sorption in the membrane containing the complex is interpreted in terms of dual mode sorption, whereby the sorbed oxygen exists as two populations: one sorbed to a polymer matrix according to Henry's law and the other to the fixed complex according to the Langmuir isotherm. The diffusion of oxygen in the membrane is found to be Fickian. Apparent oxygen diffusivity increases with an increase in the upstream oxygen pressure, which is in accordance with the dual mode transport model. (Author abstract) 16 refs.

**081985 POLYMERS AS SUBSTRATES AND MEDIA FOR DATA STORAGE.** Technological developments in the 1990s will be determined by progress in the field of microelectronics, particularly with regard to information processing and data storage. Progress in information storage is directly related to the ability to store large amounts of data in the smallest possible space, preferably in erasable form. Polymers are used as components in the standard storage systems of today: as carrier films for magnetic tapes, as photoresists and electron beam resists, and as substrates for magnetic and optical discs used for music or video replication and data storage. This progress report describes the current state of the art and compares the various developments in an attempt to forecast the possible significance of polymer memories with high data packaging densities in relation to the established technologies. **081990 APPLICATIONS OF POLYMERS IN SOLAR ENERGY UTILIZATION.** During the last decade, considerable interest has developed in both research institutions and industry, in the application of polymers in the following areas of solar energy utilization: solar energy technologies, solar energy storage, photosensitized reduction of water in microheterogeneous systems, photoelectrochemical systems, and artificial photosynthesis. This review describes these areas and shows where polymers and polymeric materials (plastics) can be employed. The interfaces of the different disciplines such as photochemistry and polymer chemistry (or polymer materials science) provide new productive areas of science and technology. This review also gives new ideas to polymer chemists and polymer technologists as to how and where to apply polymers for solar energy utilization. 406 refs.

## Association

**081993 ASSOCIATION PHENOMENA IN MACROMOLECULAR SYSTEMS - INFLUENCE OF MACROMOLECULAR CONSTRAINTS ON THE COMPLEX FORMATION.** A theoretical model is presented to describe the association behavior of interacting units attached to a polymer chain. A polymer chain of  $i$  functional groups distributed statistically along the chain is considered. A mean field approach is used to derive the probability that the  $k$ th functional group forms a complex, if  $k - 1$  groups are already complexed. As a result of the fact that the associating units are linked to the polymer chain, the fraction of complexed units is reduced compared to the corresponding association behavior of low molecular weight compounds. The magnitude of these topological restrictions depends on the molecular weight, the concentration of the functional groups, the equilibrium constant for the 'free' association, and the conformational properties of the chain. (Author abstract) 25 refs.

**081994 STUDY ON IN VITRO THROMBUS FORMATION IN A MOVING STREAM OF BLOOD FOR EVALUATING HEMOCOMPATIBILITY OF POLYMERIC BIOMATERIALS.** In 1958 Chandler invented an apparatus for in vitro thrombus formation. The apparatus consists of a small ring formed by joining the two ends of a plastic tube a few millimeters in diameter. In operation about half of the ring is filled with blood and the ring is spun vertically. At the lower part of the arc of the ring the thrombus can be formed. In employing the Chandler apparatus, the present investigation employed blood from a healthy subject instead of blood from a patient as the standard. At the same time, instead of the standard plastic tube employed in clinical tests, some materials are tested to determine the influence of parameters such as spin velocity and contact time on the compatibility of medical polymers to blood in relation to in vitro thrombus formation. In Chinese.

**081995 HUMAN MONOCYTE/MACROPHAGE ACTIVATION AND INTERLEUKIN 1 GENERATION BY BIOMEDICAL POLYMERS.** In vitro cell culture techniques were used to evaluate the effect of several clinically significant biomedical polymers on monocyte activation and Interleukin 1 (IL1) production. Isolated human peripheral blood monocytes were cultured in the presence of a panel of five biomedical polymers routinely used in a variety of clinical applications: Polyethylene (PE), silica-free polydimethylsiloxane (PDMS), woven Dacron fabric, expanded polytetrafluoroethylene (ePTFE) and the segmented polyurethane, Biomer. Monocytes generated IL1 in the presence of all five materials. Maximal levels of IL1 were generated at 24 h in monocyte-polymer cultures supplemented with serum and additionally stimulated with lipopolysaccharide (LPS). Statistically significant differences in IL1 production were observed between polymers, allowing their classification according to reactivity. (Edited author abstract). 58 Refs.

## Biosynthesis

**081998 POLYMER SYNTHESIS BY MICROORGANISMS: TECHNOLOGY AND ECONOMICS.** Although biopolymers are of much interest in industry, only a small number of biopolymers are employed by industry. Poly-β-hydroxybutyrate (PHB) is a biodegradable, biocompatible thermoplastic made by microorganisms. It can be formed into films, fibers and sheets and molded into shapes and bottles. *Alcaligenes eutrophus*, among several other microorganisms, appears to be the most satisfactory candidate for synthesizing the polymer, and glucose appears to be the best substrate. Through solvent extraction, recoveries of greater than 90% of the polymer in cells can be achieved. The PHB, a low bulk density white powder, is finally vacuum dried.

**081999** MISCIBILITY AND THERMAL DECOMPOSITION IN PHENOXY/POLY(ETHYLENE TEREPHTHALATE) AND PHENOXY/POLY(BUTYLENE TEREPHTHALATE) BLENDS. In this work the thermal decomposition of blends of a copolymer of bisphenol-A and epichlorohydrin (phenoxy) with two polyesters, poly(ethylene terephthalate) (PET) and poly(butylene terephthalate) (PBT) has been studied by means of thermogravimetric analysis. The possible influence of the degree of miscibility on the degradation processes has been considered. (Author abstract) 7 refs.

**082000** THERMALLY STIMULATED DISCHARGE CURRENT STUDIES ON PMMA-PVAc BLENDS. Thermally stimulated discharge current (TSDC) studies have been carried out on blends of polymethyl methacrylate (PMMA) and polyvinyl acetate (PVA). The effects of polarization temperature and field on the TSDC peaks of polyblends indicate that the polarization in the polyblends is due to charge-carrier trapping in deep traps which leads to induced dipole formation. The results of a.c. dielectric bridge measurements are also compared with the TSDC results. The dielectric relaxation parameters are also reported. (Author abstract) 16 refs.

**082001** ESCA AND FT-IR STUDIES ON BOUNDARY-PHASE STRUCTURE BETWEEN BLEND POLYMERS AND POLYAMIDE SUBSTRATE. Electron spectroscopy for chemical analysis (ESCA) and Fourier-transform infrared (FT-IR) attenuated total reflection (ATR) studies have been made on the film of blend polymers consisting of poly(hydroxypropyl ether) of bisphenol A (P) and poly(ethylene oxide) (E) or P and poly(ethylene adipate) (A) formed on nylon-6 (Ny) substrate to investigate the boundary-phase structure between the substrate and the polymer blends. For the case of P/A blend, A is enriched to the depths probed by both ESCA (below ca. 60 Å) and FT-IR-ATR (below ca. 0.7 µm) from the nylon-6 surface. For the P/E blend, though P is enriched to the depth probed by ESCA from the Ny surface, the enrichment of neither of the blend components can be found to the depth probed by FT-IR-ATR. These results indicate the different susceptibility between P/A and P/E blends to the influence from the Ny substrate. (Author abstract) 16 refs.

**082004** ON THE COMPATIBILITY AND THERMALLY INDUCED BLENDING OF POLY(STYRENE PHOSPHONATE DIETHYL ESTER) WITH CELLULOSE ACETATE. The miscibility of poly(styrene phosphonate diethyl ester) (PSP) with cellulose acetate (CA) was studied. Experiments were designed to prove that these polymers are a miscible pair. The study revealed that when blends were prepared from a solution with partially phosphorylated polystyrene, favourable conditions for crystallization of the cellulose acetate prevailed. Upon conversion of the crystalline regions into amorphous domains - as done by heating the sample in a differential scanning calorimeter - an amorphous homogeneous blend spontaneously formed. The results of this study revealed that PSP is miscible with CA at a lower degree of phosphorylation than previously thought; thus, one phosphoryl ester per six styrene units in PSP will still render this polymer miscible with cellulose acetate. (Edited author abstract) 8 refs.

**082005** ENTANGLEMENT, FRICTION, AND FREE VOLUME BETWEEN DISSIMILAR CHAINS IN COMPATIBLE POLYMER BLENDS. Dynamic oscillation, shear creep, and time-temperature superposition are used to study the entanglement, friction, and free volume between dissimilar chains in compatible polymer blends: PMMA/PEO, PMMA/PVDF, PMMA/SAN, and PS/PPO. It is found that interchain specific interactions, responsible for the compatibility tend to reduce the entanglement but increase the friction between dissimilar chains. The former appears to arise from local reduction of chain convolution due to segmental alignment and the latter from increased interchain attraction. The entanglement probability and the friction coefficient between dissimilar chains correlate with the strength of specific interactions. On the other hand, the free volume tends to be linearly additive but may deviate either positively or negatively, apparently influenced by segmental conformation and packing rather than specific interactions. The reduced entanglement and the free volume additivity tend to reduce the melt viscosity, while the increased friction tends to increase it. (Edited author abstract) 28 refs.

**082006** HOW WELL DO VARIOUS BLENDS OF LCP AND NYLON 12 WORK? Liquid-crystal polymers (LCPs) represent a new class of materials with unique chemical and physical properties based on unique molecular relationships. Although many macroscopic properties of LCPs are extremely advantageous, the costs associated with production of these materials are high. The blending of a conventional resin with an LCP can produce improvements in cost effectiveness and can yield novel chemical and physical results. The blending of a thermotropic LCP with less expensive nylon 12 has yielded a spectrum of materials exhibiting a wide range of interesting properties.

**082007** X-RAY AND NEUTRON SCATTERING STUDIES OF POLY(ESTER CARBONATE)/POLY(ETHYLENE TEREPHTHALATE) ALLOYS. Quenched blends of poly(ester carbonate) (PEC) and poly(ethylene terephthalate) (PET) have a single  $T_g$  and behave as single-phase amorphous alloys up to 67% PET. However, small-angle neutron scattering (SANS) data

show that the PET molecules are not statistically distributed as classical Gaussian coils in the PEC matrix. In quenched amorphous PEC-rich films (a single phase), PET-rich domains of varying PET concentration appear to be randomly distributed in the PEC matrix, and the excess SANS intensity is attributable to fluctuations in PET concentrations. Wide- and small-angle X-ray scattering data and SANS results show incomplete phase separation of PET and PEC molecules upon annealing. A possible model for annealed blends (two phases) might be domains of folded-chain, crystalline PET with interlamellar amorphous regions composed of a mixture of PET and PEC molecules. These domains are dispersed in the amorphous PEC matrix. (Author abstract) 8 refs.

**082008** POLYMER-POLYMER INTERACTION PARAMETER DETERMINED BY INVERSE GAS CHROMATOGRAPHY. Inverse gas chromatography was employed to determine the apparent polymer-polymer interaction parameter for the following blends using them as binary stationary phases: poly(vinyl acetate)-poly(n-butyl methacrylate) at 100 and 120°C, poly(vinyl acetate)-atactic-poly(vinyl isobutyl ether) at 70°C, and poly(n-butyl methacrylate)-atactic poly(vinyl isobutyl ether) at 70°C. The interaction parameter depended significantly on the chemical nature of the solvent (probe) used and the composition of the stationary phase. The lowest values were obtained when aromatic and chlorinated-alkane probes were eluted on stationary phases having weight fractional compositions of the component polymers in the range 0.4-0.6. The results predict a better compatibility for poly(n-butyl methacrylate)-atactic poly(vinyl isobutyl ether) than for the other blends. (Edited author abstract) 32 refs.

Tyagi, O.S. (CSIR, Hyderabad, India); Sajjad, S.M.; Husain, Sajid. *Polymer* v 28 n 13 Dec 1987 p 2329-2334.

**082009** STUDIES ON THE MORPHOLOGY OF BLENDS OF POLY(VINYL CHLORIDE) AND SEGMENTED POLYURETHANES. Solution-cast specimens of poly(vinyl chloride)/polyurethane (PVC/PU) blends were studied by means of infra-red, differential scanning calorimetry and dynamic mechanical measurements. Polyurethanes with polycaprolactone, poly(tetramethylene adipate), poly(tetramethylene oxide) and poly(propylene oxide) of the same molecular weight (1000) were used. The results indicate that it is possible to change the morphology of the blends significantly by proper selection of the structure of the soft segments. The polyester soft segments are more compatible with PVC than are the polyether ones. Hydrogen bonding of NH groups with the urethane carbonyl of the hard segments and with the ester carbonyl and ether oxygen of the soft segments was studied by applying a curve resolution technique to the NH and carbonyl stretching vibration absorption peaks of the blends. (Edited author abstract) 30 refs.

**082010** THERMAL CHARACTERIZATION OF BISMALEIMIDE BLENDS. 4,4'-bismaleimidophenyl methane (BM) and 3,3'-bismaleimidophenyl sulfone (BS) were blended in solution using weight ratios 3:1 (MS31), 2:1 (MS21), 1:1 (MS11), 1:2 (MS12) and 1:3 (MS13). Chain extended bismaleimide resins were also prepared by treating BS/BM with 4,4'-diaminodiphenyl ether in molar ratios of 1:0.3 (BM-E and BS-E resins). These resins were also blended with bismaleimides and the curing characteristics were evaluated by differential scanning calorimetry. Increase in BM content in BM:BS blends or increase in chain extended bismaleimide content in BM-E:BS or BS-E:BM blends resulted in a reduction of melting and curing temperatures. Indication about the extent of cross-linking was obtained from solubility measurements (in DMF) of isothermally cured resins (180°C, 1h and

220°C, 1h in an air oven). Thermogravimetric analysis of samples isothermally cured at 180°C and 220°C (1h each) was carried out in nitrogen atmosphere. Improvement in thermal stability of chain extended bismaleimides was observed on blending. (Author abstract) 16 refs.

**082011 POLYMER BLENDING CAN YIELD STRONG FILMS.** Dow's 'Saran' family of vinylidene chloride polymer and copolymers (PVDC) exhibit fine qualities but also low melt strength and a lack of toughness and rigidity. On the other hand, polystyrene is inexpensive and has good melt strength and rigidity. In this article, we discuss blends of PVDC copolymers with styrenic polymers and copolymers. For this purpose, we studied blend morphology, as well as barrier, optical, and physical properties. In the case we have studied, the polystyrene and styrene/MMA methyl methacrylate polymer added to the polyvinylidene chloride copolymer have led to increased melt strength and greater rigidity than had previously been possible in a transparent polymer. Not only was the product thermoformable, but it also was a good oxygen barrier - an excellent candidate for a good-packaging material. 5 refs.

**082012 POLYBLENDS.** In 1983, the consumption of thermoplastic polyblends in West Europe was estimated at about 450000 t. The volume consumed in 1986 has climbed to about 580000 t, corresponding an average growth of 9% per annum. Basically, three categories of starting products are available for the formation of polyblends: semicrystalline thermoplastics amorphous materials and the various modifiers and mixing aids. The presented description of technically efficient polyblends shows that blend technology continues to make possible significant advances in engineering thermoplastics, and it can reliably be assumed that the possibilities of achieving new improvements in properties or new combinations of properties by the tailored combination of more or less well known thermoplastics are by no means exhausted. 2 refs.

**082015 VISCOSITY OF HOMOGENEOUS POLYMER BLENDS: AN ALTERED FREE-VOLUME STATE MODEL.** An altered free-volume state (AFVS)

model was developed for the zero-shear viscosity of homogeneous polymer blends. The model involves a single adjustable parameter and is capable of predicting several complex features of the blend viscosity-composition behavior. These include negative and positive deviations from additivity, maxima, minima, and sigma-shaped curves. The validity of the model was tested by comparison of the model predictions with experimental data for several homogeneous blend systems. It is shown that the model is valid within a broad molecular weight range and is more accurate than some of the currently accepted models such as the kinetic network model. (Edited author abstract) 43 refs.

Sood, R. (Natl Chemical Lab, Poona, India); Kulkarni, M.G.; Dutta, A.; Mashelkar, R.A. *Polym Eng Sci* v 28 n 1 Mid-Jan 1988 p 20-31.

**082016 INTERCHAIN ELECTRON DONOR-ACCEPTOR COMPLEXES. DETERMINATION OF EQUILIBRIUM CONSTANT AND THERMODYNAMIC PARAMETERS IN THE SOLID STATE.** The interpolymeric electron donor-acceptor (EDA) complex of donor poly[(N-ethylcarbazol-3-yl)methyl methacrylate] (PHMCM-2) with acceptor poly-2-[(3,5-dinitrobenzoyloxy)ethyl methacrylate] (PDNBM-2) presents a single glass transition temperature and a decomplexation endotherm on different scanning calorimetric (DSC) thermograms. This system is considered a 'polymer blend model' which exhibits a lower critical solution temperature (LCST). Phase separation of this blend is kinetically controlled and positive deviations of the glass transition temperatures from weight average values suggest that it behaves as a thermally reversible crosslinked network. The results are supported by a composition-independent, 'horizontal line' phase diagram, thus resembling the completely complexed/denaturation process in DNA. (Edited author abstract) 49 refs.

Percec, Virgil (Case Western Reserve Univ, Cleveland, OH, USA); Schild, Howard G.; Rodriguez-Parada, Jose M.; Pugh, Coleen. *J Polym Sci Part A* v 26 n 3 Mar 1988 p 935-951.

**082017 MECHANICAL PROPERTIES OF POLY(VINYL CHLORIDE)-POLY(ACRYLONITRILE-COBUTADIENE) BLENDS WITH MODULATED STRUCTURE.** Mechanical properties were investigated by the uniaxial tensile test combined with small angle light scattering. A 50:50 plastic-rubber blend has a high initial modulus which is close to that of the rigid plastic. Nevertheless, it can deform to a large extension ratio up to 6. It cannot immediately recover to its original length after the stress-strain test. However, after release from the instrument the film gradually shrinks to its original length at room temperature. After strain recovery the film shows a stress-strain curve almost identical to the original. The stretched film healed by resting at room temperature. A helical spring model interprets well the dependence of Young's modulus on the blend composition and the periodic distance of the modulated structure. (Edited author abstract) 10 refs.

**082018 UPPER CRITICAL SOLUTION TEMPERATURE BEHAVIOUR IN POLY(ETHER ETHER SULPHONE)/POLY(ETHER ETHER KETONE-CO-ETHER ETHER SULPHONE) BLENDS.** Upper critical solution temperature phase behavior was found in blends of the homopolymer poly(oxy-1,4-phenyleneoxy-1,4-phenylenesulphonyl-1,4-phenylene) (PEES) with the copolymer poly(oxy-1,4-phenyleneoxy-1,4-phenylenecarbonyl-1,4-phenylene-co-oxy-1,4-phenyleneoxy-1,4-phenylenesulphonyl-1,4-phenylene) (CO-PEESK) for copolymer compositions ranging from 43 to 56 mol% of ether ether ketone (EEK) repeat units. Blend compositions studied ranged from 25 to 75 wt% of PEES. The consolute temperature was found to occur at a PEES/COPEESK blend composition of about 50/50 wt% and to increase with the EEK repeat unit content of the copolymer. This miscibility behavior was interpreted,

using a mean-field theoretical approach, in terms of a single positive segmental interaction parameter which ranged from 0.054 to 0.032. (Edited author abstract) 28 refs.

**082019 COMPATIBILIZER-AIDED TOUGHENING IN POLYMER BLENDS CONSISTING OF BRITTLE POLYMER PARTICLES DISPERSED IN A DUCTILE POLYMER MATRIX.** Blending brittle polymer particles in a ductile polymer matrix is a new way to obtain toughened plastics. Although the nylon-6/poly(acrylonitrile-co-styrene) (SAN) system is a ductile/brittle combination, the blend does not result in a toughened plastic. We have investigated the effect of adding a small amount of a third component, poly(styrene-co-maleic anhydride) (SMA), to the nylon/SAN system. SMA significantly improves; the tensile and impact strength of the blend. Morphological observations indicate a finer dispersion of the SAN particles when SMA is present in the blend. The improved dispersion is attributed to the formation of nylon-SMA graft copolymer. (Edited author abstract) 13 refs.

**082020 RHEOLOGY OF A MISCIBLE POLYMER BLEND.** Difference spectra of blends of cis-1,4-polyisoprene and atactic poly(vinylethylene), obtained from the measured FTIR spectra of the pure components and the blends, indicate that mixing of these polymers is not accompanied by any specific chemical interactions. Miscibility in this system arises solely due to the small combinatorial entropy of mixing. The conformation and configuration of the polymer chains in the blends are, therefore, identical to those in the pure melts. As a consequence it was found that the entanglement density of the blends varied monotonically with composition. This variation, however, was not in accordance with predictions based simply on the mechanical interaction density. The principle rheological effect of miscible blending was a large change in the monomeric friction coefficient, which arises from the strong dependence of free volume on composition. The zero shear viscosity and the terminal relaxation time of the blends reflected this change in local chain mobility. Empirical relations, which have previously been proposed for the properties of miscible polymer mixtures, were found to be without merit in describing the obtained experimental results. (Author abstract) 35 refs.

**082021 HYDROGEN BONDING IN POLYMER BLENDS. 1. FTIR STUDIES OF URETHANE-ETHER BLENDS.** The most common strong interaction in polymers, and one that is central to the properties and phase behavior of a range of important materials, is hydrogen bonding. Infrared spectroscopy is uniquely sensitive to, and considered diagnostic for, the formation of such bonds, and in recent publications we have explored the problems of using this technique to quantitatively measure the fraction of hydrogen-bonded groups in polyamides and polyurethanes. In this paper we will consider the mixing of a simple amorphous polyurethane with a polyether. This system was chosen because of its relevance to the more complicated segmented polyurethanes and in its essentials is focused upon the spectroscopic characteristics of the interaction of urethane N-H with ether functional groups. (Author abstract) 16 refs.

Coleman, Michal M. (Pennsylvania State Univ, University Park, PA, USA); Skrovanek, Daniel J.; Hu, Jiangbin; Painter, Paul C. *Macromolecules* v 21 n 1 Jan 1988 p 59-65.

**082022 HYDROGEN BONDING IN POLYMER BLENDS. 2. THEORY.** Recent work in this laboratory has focused on FTIR studies of a range of polymer blends. Although various 'rules of thumb' have been formulated as a guide to miscibility in these systems, we have not, until now, been able to use our spectroscopic measurement in the framework of the usual thermodynamic theories of mixing. This is because of the well-known inadequacies of the Flory-Huggins theory in handling strong, specific, directional interactions. We present an equilibrium approach based largely on theoretical work described in the chemical engineering literature for the self-association of alcohols in hydrocarbon solutions. The adoption to polymers is straightforward and we consider the potential of the equations for describing the phase behavior of polymers that hydrogen bond. (Author abstract) 31 refs.

**082023 MECHANICAL PROPERTIES OF POLY(ETHYLENE/ETHYLENE VINYL ACETATE FILLED WITH CALCIUM CARBONATE).** The tensile behavior of polyethylene/ethylene vinyl acetate (PE/EVA) polymer blends filled with calcium carbonate ( $\text{CaCO}_3$ ) was studied using tensile and viscoelastic tests. The relations between tensile properties (modulus, strength, etc) of oriented and unoriented PE/EVA- $\text{CaCO}_3$ , and void volume of polymer/ $\text{CaCO}_3$  interface, PE/EVA blend ratio, and  $\text{CaCO}_3$  content were investigated. The results indicated that the tensile strength and elongation of PE/EVA- $\text{CaCO}_3$  decreased with  $\text{CaCO}_3$  content and PE blend ratio for unoriented PE/EVA- $\text{CaCO}_3$  systems. In the case of oriented samples, the relative modulus ( $E_d^0/E_d^p$ ), where  $E_d^0$  and  $E_d^p$  are the modulus of oriented composites and the modulus of oriented matrix, respectively) of PE/EVA- $\text{CaCO}_3$  is larger than that of PE/ $\text{CaCO}_3$  by increasing the EVA content relative to PE and  $\text{CaCO}_3$ . The value of  $E_d^0/E_d^p$  can be simply expressed as the function of void volume and  $\text{CaCO}_3$  modulus to polymer matrix modulus. (Author abstract) 20 refs.

**082024 THEORY OF COALESCENCE IN IMMISCIBLE POLYMER BLENDS.** The theory of coalescence in melts of polymer blends was derived on the basis of the Smoluchowski theory for colloid systems. An approximation for a flux of particles used for solutions of colloids in water was analyzed. It is shown that this approximation cannot be used for polymer blends, and an approximation is suggested that could be justifiably used for them. A system of equations was derived for the time dependence of the number of individual i-mers, using the relation suggested for the diffusion flux of particles. In an approximation of the uniform increase in particle size, equations were found for the time dependence of the number of particles, the average radius of the particle, and the interface area in the volume unit of the blend. The suggested theory predicts measurable coalescence in considerably more viscous systems than mechanically applied relations of the Smoluchowski theory for aqueous colloid solutions. (Author abstract) 9 refs.

**082025 LCST AND UCST BEHAVIOR OF POLYMER BLENDS.** Using light scattering, the phase behavior of polymer blends containing random copolymers has been studied. Miscible polymers tend to phase separation at elevated temperatures. This lower critical solution temperature (LCST) behavior is typical for miscible polymer blends. The phase behavior is discussed in terms of an equation-of-state theory. For a miscible high molecular mass system the interactional parameter  $X_{AB}$  has to be negative. In polymer/copolymer systems, however, miscibility does not require any specific interactions. Repulsion between the segments comprising the

copolymer can lead to  $X_{AB} < 0$ , which favors miscibility. Some miscible polymers also exhibit phase separation at low temperatures. This upper critical solution temperature (UCST) behavior is rather uncommon for high molecular mass systems in the case of  $X_{AB} < 0$ . (Edited author abstract) 11 refs.

Kammer, H.W. (Univ of Technology of Dresden, Dresden, East Ger). *Plast Rubber Process Appl* v 9 n 1 1988 p 23-27.

**082026 PROCESSABILITY, MECHANICAL PROPERTIES AND FAILURE MODES OF XLPE/EPDM BLENDS.** Blends of uncrosslinked but crosslinkable polyethylene (XLPE) and ethylene-propylene diene rubber (EPDM) were prepared in a Brabender plasticorder by melt mixing of the components. Processing characteristics and mechanical properties of the blends were evaluated as a function of blend composition. It was observed that the viscosity of the blends increased with an increase in the EPDM content. The proportion of XLPE in the blend was found to have a profound influence on the physicomechanical properties of the composites. In order to study the mechanism of failure, the tensile and tear-fractured surfaces were examined under a scanning electron microscope. The fractographs have been correlated with the strength and type of failure of the blends. (Author abstract) 17 refs.

**082027 CHARACTERIZATION OF POLY(CARBOXYLIC ACID)/POLY(ETHYLENE OXIDE) BLENDS FORMED THROUGH HYDROGEN BONDING BY SPECTROSCOPIC AND CALORIMETRIC ANALYSES.** The solid state of the complex between poly(acrylic acid) (PAA) and poly(ethylene oxide) (PEO), and that between poly(methacrylic acid) (PMAA) and PEO formed via hydrogen-bonding was studied by differential-scanning calorimetric (DSC) and by Fourier-transform infrared (FT-IR) spectroscopic measurements. Melting temperature  $T_m$  and the degree of the crystallinity  $X_c$  of PEO in the systems PAA (or PMAA)/PEO blends obtained from aqueous or dimethyl sulfoxide (DMSO) medium were measured. It was found that 50 unit mol % of PEO is a critical composition, which gives new evidence for the 1:1 complex formation between PAA (or PMAA) and PEO. From the FT-IR spectroscopic analysis in conjunction with DSC measurements we also found that the effects of solvent and of hydrophobic interaction (due to the  $\alpha$ -methyl group of PMAA) are the important factors controlling the complexation in the solution and solid systems. These factors also affect the crystallization behavior and the microstructure of the PAA (or PMAA)/PEO blend in solid state. (Edited author abstract) 26 refs.

**082028 MISCIBILITY OF POLYESTER/NITROCELLULOSE BLENDS: A DSC AND FTIR STUDY.** The miscibility of polyester/nitrocellulose blends was investigated by differential scanning calorimetry and Fourier-transform infrared (FTIR) spectroscopy. Two nitrocelluloses (NC) derived from wood and having different nitrogen contents (12.62 and 13.42%) were used. On the basis of the glass transition temperature criterion, poly( $\epsilon$ -caprolactone) (PCL), poly(valerolactone), poly(ethylene adipate), and poly(butylene adipate) are miscible with nitrocellulose, whereas poly( $\alpha$ -methyl  $\alpha$ -propyl  $\beta$ -propiolactone) and poly( $\alpha$ -methyl  $\alpha$ -ethyl  $\beta$ -propiolactone) are immiscible. The  $T_g$  versus composition curves of PCL/NC blends do not follow a monotone function but exhibit a singular point at a critical PCL volume fraction of 0.51 for NC-1342 and 0.45 for NC-1262 in agreement with Kovacs' theory. A shift of  $17\text{ cm}^{-1}$  of the carbonyl stretching band was observed with PCL/NC blends and is taken as evidence for hydrogen bonding interaction between the PCL carbonyl group and NC hydroxyl group. (Edited author abstract) 43 refs.

**082029 MICROSTRUCTURAL INVESTIGATIONS OF PBT/NYLON 6,6 COMPOSITES.** The microstructure of composites made from blends of poly(p-phenylene benzobisthiazole) [PBT] and nylon 6,6 has been investigated with wide-angle X-ray diffraction, selected area electron diffraction, and small-angle X-ray scattering techniques. The composite samples investigated were spun in both fiber and film forms from dilute solutions of methane sulfonic acid. The structure of the composites was found to be a microfibrillar network of PBT in a matrix of partially crystalline nylon 6,6. (Edited author abstract) 10 refs.

**082030 EFFECT OF CHARGE GROUPS IN POLYSTYRENE AND POLYVINYL ACETATE IONOMERIC BLENDS.** The introduction of charge group into polystyrene and poly(vinyl acetate) chains had significantly influenced the physical and mechanical properties of the resultant polymers and the polyblends. The softening point and glass transition temperature of the resultant polymers were increased with an increase of the charge group content in the polymers. The results from dynamic mechanical analysis showed that the transitional peak of loss modulus-temperature curve of the ionic blends shifted inwardly to a temperature between the two glass transition temperatures of the straight polymers as the charge group content increased. The microphotographs of the polyblends from scanning electron microscopy showed two-separated phases for the blend of polystyrene and poly(vinyl acetate). Polystyrene was the dispersed phase in the poly(vinyl acetate) matrix. However, the domain size of the dispersed phase became smaller and smaller as the charge group content increased in the ionic polyblend. A homogeneous phase was found as the content of charge groups exceeded 10 mole% in the ionic polyblends. (Author abstract) 21 refs.

**082031 ESTIMATION OF THE INTERFACIAL FRACTION IN PARTIALLY MISCIBLE POLYMER BLENDS FROM DIFFERENTIAL SCANNING CALORIMETRY MEASUREMENTS.** While the Fried ratio may provide a qualitative measure of the extent of the actual diffuse interface in the polymer blends, it is only an approximation since the contribution of the interface is overestimated by use of the total weight fractions. The use of the actual weight fractions contributing to the  $\Delta C_{pu}$  and  $\Delta C_{pl}$  can provide an analytical expression for the amount of material in the interface. A qualitative picture of the actual interface and the resulting DSC thermogram are given. It is shown that in the interfacial zone I, the composition in the layers changes relatively rapidly from the lower phase to the upper phase such that  $T_g$  varies smoothly from  $T_{gl}$  to  $T_{gu}$ . The  $\Delta C_p$ s of the layers in this region are too small to be distinguished individually; the result is a smooth curve with positive slope between  $\Delta C_{pl}$  and  $\Delta C_{pu}$ . 4 refs.

**082032 MISCIBILITY OF POLY(2-OXAZOLINES) WITH COMMODITY POLYMERS.** Poly(N-acyl-ethylenimines) (PMeOZO, PEtOZO, and PPrOZO) have been examined for miscibility with commodity polymers of poly(vinyl chloride) (PVC), polystyrene (Pst), polypropylene (PP), and poly(vinylidene fluoride) (PVF<sub>2</sub>). The miscibility of polymer blends has been investigated by three methods: dynamic viscoelastic behaviors by rheovi-

bron for all commodity polymer blends, differential scanning calorimetry, and wide-angle X-ray scattering, the latter two being for PMeOZO-PVF<sub>2</sub> blends. PMeOZO-PVC and PMeOZO-PVF<sub>2</sub> blends are miscible at the range of the PMeOZO fraction lower than 50 wt%. With the PMeOZO-PVF<sub>2</sub> blend system, miscibility is discussed for the amorphous and crystalline parts of PVF<sub>2</sub>. PPrOZO is miscible with PSt when the PPrOZO is up to at least 25 wt %. (Edited author abstract) 20 refs.

**082033 HYDROGEN BONDING IN POLYMER BLENDS. 3. BLENDS INVOLVING POLYMERS CONTAINING METHACRYLIC ACID AND ETHER GROUPS.** In this paper we present the results of Fourier transform infrared studies of EMAA copolymer blends containing poly(vinyl methyl ether) and ethylene oxide-co-propylene oxide copolymers. The blends studied were found to be extensively mixed at the molecular level in the amorphous state. Quantitative measurements of the fraction of EMAA carboxylic acid groups that are hydrogen bonded to ether groups have been obtained in blends of different compositions, and the results are discussed in terms of competing equilibria. (Edited author abstract) 23 refs.

**082034 NEUTRON AND X-RAY SCATTERING STUDIES ON SEMICRYSTALLINE POLYMER BLENDS.** Mixtures of poly(ethylene oxide), PEO, with protonated or deuterated poly(methyl methacrylate), PMMAH or PMMAD, respectively, crystallized at 50°C have been investigated by small-angle X-ray scattering, SAXS, and small-angle neutron scattering, SANS. It is shown that PMMA is incorporated into the amorphous phase between the crystalline lamellae. In addition, the thickness of the crystalline lamellae remains constant as a function of temperature which is in keeping with a small interaction parameter between the PEO and PMMA. The diffuse-phase boundary between the crystalline and amorphous phase is ca. 15 Å greater for the SAXS measurements than that measured by SANS. (Edited author abstract) 29 refs.

**082035 ELECTRONIC PROPERTIES OF AN ELECTRON DONOR-ACCEPTOR POLYMER BLEND.** The authors have studied the phase-separation behavior of the photoconductive polymer blends containing electron donor-acceptor (EDA) complexes, because they can have interfaces similar to the p-n junctions of semiconductors and may have unusual electronic properties different from those of doped polymer systems. It is shown that when the films were heated, another phase separation started in the matrix, and islands were finally absorbed into the newly separated phase. The phase-separation structure changed to a reticular tetrapod structure which was retained after being cooled to room temperature at ca. 7 deg/min. Examination of these films under a phase-contrast microscope with different varying focal point across the film thickness showed that each of two phases in this tetrapod structure was highly interconnected. 7 refs.

**082037 PHASE MORPHOLOGY OF A MODEL POLYBLEND FABRICATED IN INDUSTRIAL MIXERS: TIME AND MELT FLOW DEPENDENT SUPRADOMAIN STRUCTURES.** A study is made of the effects of the mixing process on phase morphology of the polyblend/alloy, in an industrial mixer, for which a prediction of the streamline pattern is feasible. While the authors report some semiquantitative results of the attempted correlation between the streamlines and the supradomain aggregates pattern, they also follow the MIXERIU program routing in seeking a relationship between the minor phase domain size and the mixing process description such as stress level, stretch rate, residence time, etc. Experimental data indicate that the goals and scope of the polyblend/alloy characterization as well as the selection of the component polymers were discussed earlier. 21 Refs.

**082038 FLOW BEHAVIOR AND MICROSCOPIC-STRUCTURE OF BINARY POLYMER BLENDS WITH A THERMOTROPIC LIQUID CRYSTALLINE POLYMER.** Two binary blend systems (polycarbonate (PC) or polyamide (PA) blended with a thermotropic liquid crystalline polymer of the wholly aromatic polyester (LC)) were prepared through the extrusion involving melt-blending. The measurements of the flow behavior of these blend systems of LC/PC and LC/PA using a capillary extrusion rheometer clarified that the apparent viscosity  $\eta_a$  is strongly governed by shear stress  $\tau_w$  as well as by blending ratio, but does not follow the logarithmic rule of mixtures. For the LC/PC systems, the mechanical properties of the extrudate after viscometric testing and of the injection-molded specimen are independent of the blending ratio. Characteristics of the blend are considered to be strongly affected by the dispersion state. A scanning electron microscope showed that there exists an obvious relation between the phase-structure and the state of melt or molecular orientation due to the shear flow. **082040 COOPERATIVE CHAIN RELAXATION IN MISCIBLE POLYMER BLENDS.** The orientation relaxation of dissimilar chains in the molten miscible blends, poly(methyl methacrylate)/poly(vinylidene fluoride) and poly(methyl methacrylate)/poly(vinylidene fluoride-co-trifluoroethylene), was investigated by measuring (1) the change of infrared dichroic ratio with time after the uniaxial stretching of film specimens, (2) the shear stress relaxation spectrum, and (3) the birefringence relaxation

in shear. The dissimilar polymers showed an identical time variation of the normalized Hermans orientation function. The blend showed a relaxation spectrum with a single characteristic relaxation time  $\tau_{\infty}$  depending on the blend composition. The birefringence relaxed monotonically, remaining positive. These results suggest that the dissimilar polymers do not relax independently but cooperatively. This behavior may be induced by a constraint due to the specific interactions between the dissimilar polymers, e.g., weak hydrogen bonding. For the cooperative chain relaxation, a third power relationship was found. (Edited author abstract). 14 Refs.

**082041 THERMODYNAMICS OF MISCIBLE POLYMER BLENDS USING A CONCENTRATION-DEPENDENT  $\chi$  PARAMETER.** The Flory equation-of-state theory, as expressed by D. Patterson and co-workers, has been applied to two miscible polymer blends: poly(vinyl chloride)/poly( $\epsilon$ -caprolactone) and poly(methyl methacrylate)/poly(vinylidene chloride). For both blends, the variation of the polymer-polymer interaction parameter,  $\chi'_{23}$  as a function of composition, is mostly small and can be accounted for by the Flory theory. However, for poly(vinyl chloride)/poly( $\epsilon$ -caprolactone) blends, at high poly( $\epsilon$ -caprolactone) content, the large variation of  $\chi'_{23}$  as a function of concentration can be explained by a variation of the surface-to-volume ratio of the polymers in the mixture with blend composition. The variations of the surface-to-volume ratios determined in this study agree with those reported in the literature using small-angle x-ray scattering. (Edited author abstract). 46 Refs.

**082043 CONTRIBUTION TO THE UNDERSTANDING OF POLYETHYLENE/IONOMER/POLYAMIDE-6 BLENDS.** Binary polyethylene/EMA and EMA/polyamide-6 blends were studied with the hope that the role of EMA as a compatibilizer in polyethylene/EMA/polyamide-6 ternary blends might be better understood. Differential scanning calorimetry (DSC), laser small-angle light scattering, and mechanical property results are discussed. DSC measurements show that one component of the binary blends does not modify the crystallinity of the other. However, laser small-angle light scattering shows that the morphology of the mixtures changes under similar conditions. Tensile properties of polyethylene/EMA binary blends vary linearly as a function of composition, whereas those of EMA/polyamide-6 blends deviate slightly from linearity. These results

indicate no interaction between the crystalline components of the mixtures, and weak interactions in the amorphous phase. (Edited author abstract) 65 refs.

**082044 NUCLEAR MAGNETIC RESONANCE STUDIES OF IONOMERS. 6. POLYURETHANE-POLYPHOSPHONATE BLENDS.** Blending of a poly(ether urethane) with a polyphosphonate obtained by phase transfer catalyzed polycondensation of 4,4'-biphenol and chloromethylphosphonic dichloride generates a phase-separated material. One phase contains the soft segment of the polyurethane. This has been excluded from a high- $T_g$  phase that contains ionic species formed mainly by proton transfer and elimination reactions between the hard segment of the polyurethane and the polyphosphonate. Two glass transitions appear in the blend: one close to the  $T_g$  of the polyphosphonate and one belonging to the excluded soft segment of the polyurethane. The low temperature  $T_g$  decreases with the increasing content of the polyphosphonate, whereas the high temperature transition increases slightly, indicating an increasing purity of the soft segment and the presence of ionic interactions in the hard segment. The presence of ionic interactions is confirmed by NMR analysis of the blend. Comparison of the spectra of the blends with those of the pure components, along with two-dimensional experiments, indicate a reaction involving the chloromethyl groups of the polyphosphonate and the nitrogens of the polyurethane. (Author abstract) 16 refs.

**082045 LINEAR LOW DENSITY POLYETHYLENES AND THEIR BLENDS: PART 4. SHEAR FLOW OF LLDPE BLENDS WITH LDPE AND LDPE.** The steady state and dynamic shear behavior of linear low density polyethylenes (LLDPE) blended with low density polyethylene (LDPE) and with another LLDPE resin were measured in capillary and parallel plate geometries at  $T=150, 190$ , and  $230^\circ\text{C}$ . The extrudate swell and the Bagley correction were determined. It was observed that the pressure correction plays a significant role in capillary flow of LLDPE/LDPE blends - an indication of immiscibility. Several other rheological functions also suggested a phase separation for the system. Nevertheless, the blend behaved as a 'compatible' mixture of emulsion type. By contrast, blends of two LLDPE resins show expected miscibility. However, even in this case additivity was not always observed. A new simple method of calculating the relaxation spectrum was developed. The method is analytical and its accuracy depends on adequacy of the semiempirical relation (proposed previously) to describe dynamic viscosity dependence on the test frequency. For all samples the spectrum allowed computation of storage modulus in good agreement with experimental findings. (Author abstract) 66 refs.

**082046 BLENDS OF POLYCARBONATE AND POLY(HEXAMETHYLENE SEBACATE): II. EFFECT OF MOLECULAR WEIGHT ON COMPATIBILITY.** Blends of polycarbonate (PC) and poly(hexamethylene sebacate) (HMS) with two different molecular weights were prepared and their thermal properties were studied via differential scanning calorimetry. It was found that the high molecular weight PC (HPC) and high molecular weight HMS (HHMS) were partially miscible as evidenced by the decrease in glass transition temperature of HPC in the blends. This partial miscibility is attributed to the interaction of the carbonyl dipole of the ester group and the highly polarizable aromatic carbonate structure. When the low molecular weight PC or HMS was used, the compatibility was enhanced because of the increased entropic contribution to the Gibbs free energy of mixing. In all the blends prepared, the PC crystallized

as a result of the plasticizing effect of HMS. Bisphenol-A diphenyl carbonate (dimer) was synthesized and used as the dimeric model of PC. This material was found to be an excellent diluent for HPC. (Edited author abstract) 30 refs.

**082047 STRUCTURE-PROPERTY-PROCESSING RELATIONSHIPS OF POLYPROPYLENE-POLYBUTYLENE BLENDS.** In this paper we discuss PP-PB blends in which both components are highly crystallizable. It was our intention to try to prepare homogeneous PP-PB blends, assuming miscibility in the melt, by using the ultraquenching technique and to study the properties of the resulting blends following crystallization from the glass. Due to the possibility of preparing homogenous blends by ultraquenching, it should be interesting to compare the morphology, properties, and crystallization of the glass-crystallized blends with the melt-crystallized blends. We conclude that, in general, the above results suggest there is a considerable degree of compatibility, possibly even miscibility, of PP and PB in the melt, but that miscibility is difficult to obtain by ordinary melt mixing processes. (Author abstract) 29 refs.

**082048 CHARACTERIZING POLYETHYLENE-BASED BLENDS WITH TEMPERATURE. RISING ELUTION FRACTIONATION (TREF) TECHNIQUES.** The temperature rising elution fractionation (TREF) short chain branches (SCB) technique has been applied to blends of PE by recognizing that the two commercial types of low density polyethylene, high pressure (HP-LDPE) and linear low density (LLDPE), have different short chain branching distributions. We have constructed a TREF apparatus that can be used in a number of different types of blend studies. The first is an Analytical-TREF, which gives a profile of the amount of polymer with a given SCB level and can be used to quantify HP-LDPE/LLDPE blends. We have also modified the technique to construct a stop-flow TREF apparatus, which enables one to separate fractions on the basis of the branching levels. The fractions can then be analyzed by size exclusion chromatography, IR,  $^{13}\text{C}$  NMR, or DSC. The use of these TREF techniques to characterize blends of HP-LDPE/LLDPE, LLDPE/EVA, PE/EPDM, and PE/polyisobutylene is discussed. (Edited author abstract) 12 refs.

**082049 POLY(ETHYLENE TEREPHTHALATE) BLENDS FOR PERMEABILITY BARRIER APPLICATIONS.** Poly(ethylene terephthalate) (PET) offers good properties as a material of choice for various packaging, electronic, and other applications. In these applications in general, the PET articles achieve improved toughness and other physical properties through molecular orientation resulting from stretching at temperatures slightly above its  $T_g$ . Without such orientation, these articles suffer from poor impact toughness. We have been investigating modifications of PET for improving toughness and retaining the permeability properties. PET having intrinsic viscosities of 0.5 to 0.7 has been modified with low modulus polymers, particularly ethylene copolymers such as ethylene-methacrylic acid (EMAA) copolymers. The effect of crystallinity on toughness was determined. The crystallinity was established by Differential Scanning Calorimetry (DSC) techniques. Many of these modified PET compositions have good toughness and permeability barrier properties for various packaging and other controlled permeability applications such as containers and films. (Author abstract) 12 refs.

**082050 STRUCTURE-PROPERTY RELATIONSHIPS IN POLYAMIDE/ACRYLONITRILE-BUTADIENE-STYRENE (ABS) BLENDS.** The structures and physical properties of four blends of poly(acrylonitrile-co-styrene-g-butadiene) (ABS) materials with polycaprolactam (PA6) have been characterized. The blends were separated into components by selective solvent extraction and were found to contain different structures. Blend A contained no PA6 grafts. Blend B contained PA6 grafted onto both soluble and insoluble ABS. Blend C contained PA6 grafted onto soluble poly(styrene-co-acrylonitrile) (p-SAN). In Blend D, PA6 was grafted on both the insoluble ABS and the p-SAN phases. Transmission electron microscopy showed different morphologies in the blends. Blend A had a co-continuous, somewhat laminar structure, while Blend D consisted of an ABS phase dispersed in a PA6 continuum. Blends B and C had intermediate structures. All four blends, however, had very similar rheological and physical properties despite the variation in structure. (Author abstract) 10 refs.

**082051 EFFECT OF VISCOSITY RATIO ON THE MORPHOLOGY OF POLYPROPYLENE/ POLYCARBONATE BLENDS DURING PROCESSING.** The size of the minor phase in an immiscible polymer blend can have a significant effect on properties such as the impact strength. Few studies, however, have quantitatively considered the parameters controlling the size of the dispersed phase. In this paper, light and scanning electron microscopy have been used to examine the size of the minor phase in polypropylene/polycarbonate blends after melt processing. The size was examined as a function of both the viscosity ratio ( $\eta$ ) and the torque ratio (TR). The viscosity ratio is studied in the regions of  $\eta > 1$  and  $\eta < 1$ .  $\eta$  has a marked effect on the morphology of the dispersed phase with the phase size increasing by a factor of 3 to 4 times from  $\eta = 4.5$  to  $\eta = 17.3$ . Reduction in the size of the minor phase was achieved below  $\eta = 1$  with the minimum particle size occurring at  $\eta = 0.15$ . The results for these systems indicate the presence of upper and lower limits of  $\eta$  beyond which deformation becomes difficult. This is shown to be similar in some respects to the behavior of Newtonian fluids in shear flow, although the upper limit extends beyond that observed in the Newtonian fluid studies. (Author abstract) 24 refs.

**082052 LIGHT-SCATTERING CHARACTERIZATION OF POLYBLENDS IN THE PRESENCE OF MULTIPLE-SCATTERING CONDITIONS.** A novel approach is described for the noncontact evaluation of structural morphology in polyblends by light scattering. Optical methods are attractive for the on-line characterization of translucent materials because they are noninvasive, rapid, and applicable to high temperature materials. One limitation of conventional light-scattering techniques is their requirement for relatively thin samples in order to avoid multiple-scattering effects that smear out the details of the light diffraction pattern. The approach described in this paper is meant to circumvent this limitation by resorting to turbidimetric measurements, which provide useful information on the average size, shape, concentration, and orientation of the dispersed phase particles even in the presence of multiple scattering. The sample thickness is no longer restricted, and methods are described by which the near-surface volume of infinitely thick parts may be inspected with access to a single side of the material. Results are presented for polypropylene-polycarbonate (PP/PC) samples of different thicknesses and microstructural morphology, including fibrillar-type oriented structures. (Author abstract) 31 refs.

**082053 POLYSTYRENE-POLYETHYLENE MELT BLENDS OBTAINED THROUGH REACTIVE MIXING PROCESS.** Reactive polystyrene (OPS) and reactive polyethylene (CPE) with oxazoline and carboxylic acid functionality, respectively, were melt blended in a Rheomix mixer under a variety of conditions. The properties of these blends were examined and correlated with the compositions and mixing conditions such as shear rate, time, and temperature. Mechanical properties such as elongation at break of reacted blends are improved over the nonreactive polyethylene (PE) and polystyrene (PS) blends. An intermolecular reaction between the OPS and CPE results in a graft polymer, which imparts improvement in the overall properties of these reacted blends. The maximum grafting reaction corresponds to 40% CPE blend, which is being evaluated as a potential compatibilizer. (Edited author abstract) 17 refs.

**082054 PHASE BEHAVIOR AND MECHANICAL PROPERTIES OF POLYARYLATE AND POLYCARBONATE BLENDS.** The phase behavior and mechanical properties of a series of polyarylate/polycarbonate blends were studied. The polymers are known to transesterify, the extent of which depends upon the thermal and shear history and affects phase behavior and properties. Single screw extrusion, twin screw extrusion, and solution casting were employed for blend preparation. Two transition temperatures, corresponding to a polycarbonate-rich phase and to a polyarylate-rich phase, were seen in blends that were solution cast or compounded in a single screw extruder at 285°C. But after injection molding a single  $T_g$  was observed. When annealed at 180°C for several hours the molded blend was found to phase separate. Blends that were compounded in a twin screw extruder exhibited a single  $T_g$  and could not be phase separated. The flexural and tensile properties of blends that were prepared in a twin screw extruder show a small positive synergism. But the impact properties were substantially below the rule of mixtures values, probably the result of advanced exchange reaction and thermal degradation. (Author abstract) 12 refs.

**082056 INVESTIGATION ON POLY(VINYLENE SULPHIDE): AB INITIO ENERGY BAND STRUCTURE, USE OF EFFECTIVE CORE POTENTIALS, LATTICE SUM TRUNCATION.** The energy band structures of two structural isomers of poly(vinylene sulphide) are calculated using the ab initio Hartree-Fock crystal orbital method. The basis set dependence and the convergence of quantities like the total energy per elementary cell and the atomic electron population with the number of interactions with neighbours are investigated.

The band structure calculations are repeated employing effective core potentials first for sulphur atoms only and then for all non-hydrogen atoms. The results of the valence-electron only and the mixed computations agree very well with the all-electron calculations. (Edited author abstract) 23 refs.

Otto, P. (Friedrich-Alexander-Univ Erlangen-Nuernberg, Erlangen, West Ger). *Synth Met* v 22 n 2 Dec 1987 p 129-143.

**082057 CONFORMATIONAL FEATURES OF POLY(METHYLPHENYLSILYLENE).** The conformational energies and helix parameters were calculated for the various states of the poly(methylphenylsilylene) (PMPS) chain, in terms of the rotations around two successive skeletal bonds. The calculations were performed for the three different relative dispositions of the phenyls attached to three successive silicon atoms. The minima are invariably shifted from perfectly staggered positions. The significant shift of the minimum in the  $tt$  state results in a nonrectilinear shape for the chain segment. The possible correlations between the a priori probability of bond conformations and the spectroscopic observation on the variation of UV absorption maximum with degree of polymerization for the oligomers and the change in the peak characteristics upon reducing the temperature to 77 K are explored. (Edited author abstract) 19 refs.

**082058 HEAD-HEAD INTERACTIONS IN ZWITTERIONIC ASSOCIATING POLYMERS.** Theoretical calculations are presented, both at the molecular mechanics empirical level and at the Hartree-Fock semiempirical level (MNDO), on molecules containing (ammonioalkyl)sulfonate zwitterions as models for semitelechelic associating polymers. In particular the interactions between the zwitterionic head groups and the evolution of the energetics and structures of the molecules are examined as a function of their aggregation. The clustered zwitterions adopt an extended (all-trans) conformation with their dipoles aligning in an antiparallel fashion in order to favor interchain electrostatic interactions. For large aggregation numbers in apolar solvents, associating polymers with zwitterionic head groups are predicted to form reverse micelles that possess either a tubelike or a disklike structure. (Edited author abstract) 39 refs.

**082059 CALCULATION OF THE MOLECULAR MASS CHARACTERISTICS OF POLYMERS FROM NON-TERMINATING POLYMERIZATION BY POLYFUNCTIONAL INITIATORS IN CONDITIONS OF CHAIN TRANSFER TO THE SOLVENT.** The authors have calculated the form of the MD, the mean degrees of polymerization  $P_n^-$ ,  $P_w^-$  and  $P_z^-$  of the global polymer and also separately the primary (formed on the initial initiator) and secondary (resulting from chain transfer) fractions for the case of non-terminating polymerization with chain transfer to the solvent using polyfunctional initiators. The dependences of these characteristics on the degree of functionality of the initial initiator and the intensity of chain transfer have been determined. The limits of the desirability of using polyfunctional initiators in real technological processes of synthesis of high molecular weight polymers are evaluated. (Author abstract) 6 refs.

**082060 EFFECT OF VISCOELASTICITY ON BUBBLE COLLAPSE AND INDUCED IMPULSIVE PRESSURE.** The effect of viscoelasticity on the collapse of a gas bubble and the impulsive pressure induced by the bubble is found by numerically analyzing the bubble motion in viscoelastic fluids of a three-constant Oldroyd model. The computational results show that the relaxation effect in a viscoelastic fluid increases the impulsive pressure while the retardation effect decreases it. The damping of the bubble oscillation decreases with increasing relaxation time or with decreasing retardation time. The amplitude of the bubble oscillation is a maximum when the retardation time equals zero. The mechanism of cavitation damage in polymer aqueous solutions is discussed. (Edited author abstract) 25 Refs.

**082061 COLLAPSE OF BUBBLES IN VISCOELASTIC FLUIDS (THE CASE OF JEFFREYS MODEL FLUID).** A theoretical study is made concerning the collapse of a bubble in a Jeffreys model of viscoelastic fluids. The equation of motion for the bubble in the Jeffreys model fluid and the pressure equation are derived. The numerical calculations of these equations are carried out. Then the effects of relaxation time, retardation time and viscosity on the behavior of the bubble and the maximum pressure generated at first rebound are clarified. The pressure distributions around the bubble are also examined. (Edited author abstract) 9 Refs.

**Chemical Analysis**

**082062 RELATIVE REACTIVITIES OF AMYLOSE HYDROXYL GROUPS IN THE REACTION WITH DIKETENE.**  $^{13}\text{C}$  nuclear magnetic resonance (n.m.r.) spectra at 75.4 MHz of partially modified amylose with  $\beta$ -ketone ester groups (degree of substitution (DS) ranging from 0.52 to 2.42) were studied in order to evaluate the selectivity of the reaction of amylose with diketene in the homogeneous phase. Analysis of the spectra of ring carbons in the anhydroglucose units shows that the reactivity of individual hydroxyl groups decreases in the order C-6 > C-3 > C-2 for DS values up to approximately 1.8. For higher DS values a negative deviation is observed for the hydroxyl group at C-6 and a positive deviation for the hydroxyl groups at C-2 and C-3. The DS values determined by  $^{13}\text{C}$  n.m.r. spectra are in good agreement with those found by chemical analysis. (Author abstract) 24 refs.

**082063 XPS STUDY OF THE PENETRATION AND REACTION SPEED OF POLYMER DERIVATIZATION REAGENTS.** Functionalized polymer surfaces were prepared by electropolymerizing substituted phenols and were used to study the penetration depth and speed of reaction of derivatization reagents (trifluoroacetic anhydride and pentafluorophenylhydrazine). Depth information was obtained by angular variations of XPS intensities and lineshape analysis according to Tougaard's method. The penetration of both reagents into the test

polymers is rapid, but the reaction of pentafluorophenylhydrazine with carbonyl groups is slow. (Author abstract) 17 refs.

**082065 POLYMER-SUPPORTED DIPYRIDYLMETHANE DICARBOXYLIC ACIDS - PREPARATION AND COMPLEXATION WITH METAL IONS.** Polymeric 1,1-di(6-carboxy-2-pyridyl)methanes, bispicolinic acids, have been prepared by O-alkylation of 1,1-di(6-cyano-2-pyridyl)methanol with macroporous chloroacetylated and chloromethylated poly(divinylbenzene). Attempts to prepare reagents by C-alkylation of the silyl ether of this alcohol failed. A ligand attached to the polymer via a C-8 spacer arm generated from 1-(tetrahydropyran-2-yloxy)-8-octyl magnesium bromide has been prepared by substitution of an animated polymer. The capability of the ligands to extract metal ions from aqueous solutions has been determined and they have been found to be efficient reagents for the complexation of several metal ions, in particular copper and nickel ions. Their coordinating behavior is somewhat dependent upon the structure of the spacer connecting the ligand with the polymeric support. (Author abstract) 11 refs.

**082066 FOURIER TRANSFORM INFRARED SPECTROSCOPIC STUDY OF THE REACTION BETWEEN POLY(VINYL PYRIDINE)S AND EPOXY COMPOUNDS.** Chemical reactions between poly(vinyl pyridine)s and 1,4-butanediol diglycidyl ether and other epoxy compounds were studied by Fourier transform infrared spectroscopy and other techniques. The epoxy group was found to react with the pyridine side group of poly(4-vinyl pyridine), forming crosslinked networks which contain cyclic amide structures. The reaction was also observed in the interfacial region of poly(vinyl pyridine) and  $\gamma$ -glycidyloxypropyl trimethoxysilane hydrolyzate (y-GPS) coatings on PET fiber substrates. Poly(2-vinyl pyridine) does not show the same reaction. (Author abstract) 25 refs.

**082067 SELECTED PAPERS PRESENTED AT THE 3RD INTERNATIONAL CONFERENCE ON POLYMER-SUPPORTED REACTIONS IN ORGANIC CHEMISTRY.** This issue contains 64 selected conference papers of which 38 appear in abstract form only. The papers deal with polymer-supported reactions in organic chemistry. The main topics include: synthesis and characterization of polymeric reagents; polymer-supported reagents in synthesis; polymeric reagents in catalysis; polymer conjugated biocatalysts; polymers in peptide synthesis; polymers in nucleotide synthesis; special polymeric assemblies; polymer-assisted recognition and separation; diagnostic and pharmaceutical applications; and biomimetic chemistry. All the papers are abstracted separately. Technical and professional papers from this conference are indexed and abstracted with the conference code no. 10541 in the Ei Engineering Meetings (TM) database produced by Engineering Information, Inc.

**082068 INSOLUBLE POLYMER-SUPPORTED 2,2'-BITHIAZOLINYLIDENES.** Polymer-supported thiazolium salts can be conveniently prepared by quaternizing thiazoles with Merrifield resins or by building up the thiazole ring around the nitrogen of an amino resin. Chiral polymer-supported salts result when the amino group is that of an amino acid previously anchored to a polymeric frame. Polymer-supported thiazole salts treated with aqueous sodium hydrogencarbonate solutions afford resins which, by themselves, are active as benzoin condensation catalysts. This activity is best explained, according to analytical and spectral data, by the presence of polymer-supported 'dimers' (2,2'-bithiazolinylidenes). 18 refs.

**082069 ELECTRICAL CONTROL OF IMMOBILIZED ENZYME SYSTEMS: APPLICATIONS TO INFORMATION PROCESSING.** Artificial systems containing an enzyme and monitored by electric signals have been studied to create some functions with applications in biotechnology and 'bioelectronics'. These systems were characterized by their structure, the enzyme kinetics involved, the conductivity level and the nature of the boundary conditions. The control of these systems by electric signals (dc or pulses) has led to various results: regulation of enzyme activity, a 'conductivity effect' leading to amplification of regulatory effects, reaction-separations and commutations. (Author abstract) 19 refs.

**082070 PERSPECTIVES IN ULTRA-HIGH LOAD SOLID (GEL) PHASE PEPTIDE SYNTHESIS.** A novel approach to ultra-high load solid (gel) phase peptide synthesis is reviewed and some recent developments discussed. The approach utilizes a phenolic bead-form core network at an initial matrix loading of 5.0 mmol g<sup>-1</sup>, the theoretical maximum. Consecutive repeating units along the polymer backbone each form a point of attachment for a growing peptide chain, synthesis proceeding via the stepwise elaboration of a series of quasi-homogeneous peptide gel networks. The success of the method, which has proved effective in the laboratory preparation of gram and multi-gram quantities of peptides, is ensured by the judicious choice of reaction conditions, reagents and solvents, so as to secure efficient gelation for all intermediate peptide gel networks. These may be regarded as quasi-homogeneous, both in covalent network architecture and in network distribution within the gel particles. (Author abstract) 17 refs.

**082071 MODERN METHODS OF NUCLEIC ACID SYNTHESIS ON POLYMERIC SUPPORTS.** Deoxyoligonucleotides can be synthesized rapidly and in high yield because of recent advances in nucleic acid chemistry. Key innovations include solid phase synthesis of silica-based supports and the development of stable deoxynucleoside phosphoramidites as synthons. When incorporated into manual, semiautomatic, or automatic instruments, these new procedures can be used to prepare probes, mixed probes, deoxyoligonucleotides for priming DNA synthesis, analogues of deoxyoligonucleotides, and genes. Oligoribonucleotides have also been prepared. The

most successful approach so far developed involves using 2'-protected nucleosides as synthons and bis(diisopropylamino)methoxyphosphine as a phosphorylating reagent. A regioselective condensation route leading to the exclusive synthesis of 3'-5' internucleotide linkages is possible. (Author abstract) 36 refs.

**082072 SPACER EFFECT ON THE SYNTHESIS OF OLIGODEOXYNUCLEOTIDES BY THE PHOSPHITE METHOD.** Nineteen oligonucleotides of 15-27 bases long were synthesized on aminoalkyl spacers of various chain lengths, Si-O(CH<sub>2</sub>)<sub>n</sub>NHCONH(CH<sub>2</sub>)<sub>n</sub>NHCO(CH<sub>2</sub>)<sub>m</sub>NH<sub>2</sub>, linked to Fractosil silica gel supports (F6, F12, F15, F18, F21, F24, F32, F38), to Porasil (P15) silica gel support, and to modified controlled pore glass (CPG17, CPG24). The purity and the homogeneity of the end product in the reaction mixture was quantitatively determined from the autoradiograph pattern of bands on polyacrylamide sizing gel. The data indicated that the most pure products are obtained either on the shortest spacer, F6, or on the 24, 32, or 38 atom length spacers. Spacer lengths of 15, 18 and 21 atoms gave very poor results, with large amounts of impurities. The results are interpreted on the basis of conformational changes in the spacer alkyl chain as a function of its length. (Author abstract) 57 refs.

**082073 POLYMERS AS SUPPORTS FOR ENZYMIC OLIGO- AND POLYSACCHARIDE SYNTHESIS.** Polymer-supported enzymic oligosaccharide synthesis may lead to products of biological interest otherwise not readily attainable. Thanks to the 'polymer handle', the products are readily isolated, purified and characterized. This makes it possible to deal efficiently with comparative acceptor specificity and demonstrate de novo synthesis: the specific example of glycogen synthetase is discussed. The derivatised polymers used were crosslinked polyacrylamide gel beads, water-soluble poly(vinyl alcohol) and water-soluble polyacrylamide. The saccharide products were removed from the polymer supports by photolysis of substituted o-nitrobenzyl linkages or by enzymic hydrolysis using  $\alpha$ -chymotrypsin. (Author abstract) 38 refs.

**082074 COMPARISON OF ENANTIOMER SEPARATION BY INCLUSION CHROMATOGRAPHY AND BY RESOLUTION VIA DIASTEREOISOMERIC SALT FORMATION.** Enantiomers of 6,7-dihydroxy-(3,4,5-trimethoxybenzyl)-1,2,3,4-tetrahydroquinoline hydrochloride were separated via diastereoisomeric salt formation using optically active tartaric acid, by inclusion-complex formation using water-soluble cyclodextrin polymer, and by inclusion chromatography on  $\beta$ -cyclodextrin bead polymer. On a microscale, the chromatographic resolution has significant advantages over the traditional methods. (Author abstract) 20 refs.

**082075 ANTIAROMATIC ANNULENONES.** The existence of several unstable annulenones has been demonstrated by using polymeric reagents. Furthermore, a 'polyphasic dynamic reactor' allowed determination of the lifetime of such annulenones. Thus, the relation between structure and stability for those compounds is established. (Author abstract) 5 refs.

**082076 DESIGN OF CHIRAL POLYMERS FOR THE KINETIC RESOLUTION OF RACEMIC CONGLOMERATES.** The design of chiral polymers as stereospecific inhibitors for efficient kinetic resolution of conglomerates by crystallization is described. The selection of the polymers is done on the basis of the crystal structure and the morphology of the substrate. The resolutions with the polymers are better than those previously obtained with low molecular weight additives. This is illustrated for the comparative resolutions of (R,S)-glutamic acid Glu-HCl, (R,S)-threonine, (Thr), (R,S)-asparagine monohydrate, (Asn-H<sub>2</sub>O), and (R,S)-p-hydroxyphenylglycine-p-toluenesulfonate, (pHP-gTs). Further, (R,S)-histidine, which could not be resolved with the low molecular weight inhibitors, was successfully resolved with two polymeric reagents. A simultaneous resolution of the enantiomers in a device composed of two compartments separated by a membrane is described. (Edited author abstract) 39 refs.

**082077 POLYMER-PENDANT LIGAND CHEMISTRY, 2: REACTIONS OF VANADYL ACETYLACETONATE WITH CATECHOL LIGANDS BONDED TO POLYSTYRENE-DIVINYLBENZENE RESINS AND STRUCTURAL DETERMINATION OF THE VANADIUM CATECHOLATES ON THE POLYMER.** The reactions of catechol ligands, bonded to either 2% or 20% crosslinked methylated polystyrene-divinylbenzene resins (CAT-PS-DVB), with vanadyl acetylacetonate [VO(AcAc)<sub>2</sub>] were studied. Vanadyl ion removal from solution at equilibrium was 0.104 mmol V/g of resin and 0.075 mmol V/g of resin for the 2% and 20% CAT-PS-DVB resins, respectively. It was found that the 20% crosslinked modified resin was limited in the vanadyl ion ligand exchange reaction by diffusion into the resin, while this was not the case for the 2% crosslinked modified resin. The effect of the base, triethylamine, dramatically increased the amount of vanadyl ion removed from solution, via ligand exchange; this is thought to occur by deprotonation of the catechol ligand. The bidentate ligand, bipyridine, had no effect on the removal of vanadyl ion in the ligand exchange reaction and thus apparently does not form a 1:1 complex with the vanadium catecholate bonded complex. The structures of the vanadium catecholates on the resin were tentatively established by infrared and electron paramagnetic resonance (EPR) spectroscopy. (Edited author abstract) 19 refs.

**082079 ENZYME-MIMICKING POLYMERS EXHIBITING SPECIFIC SUBSTRATE BINDING AND CATALYTIC FUNCTIONS.** This report describes the first attempts to combine two approaches, that of molecular imprinting and the preparation of polymer-bound catalysts. This leads to reactive polymers showing enzyme properties, i.e., substrate specificity and catalytic activity. Polymers were prepared by radical co-polymerization of 4-(5)-vinylimidazole with a crosslinker (divinylbenzene) and a guest molecule (derivatives of N-protected amino acids) in the presence of transition metal ions (Co<sup>2+</sup>). Thus, a transition metal ion complex is formed together with vinylimidazole and the guest molecule. (Edited author abstract) 10 refs.

**082081 ENZYME-ANALOGUE BUILT POLYMERS, 24: ON THE DISTANCE ACCURACY OF FUNCTIONAL GROUPS IN POLYMERS AND SILICAS INTRODUCED BY A TEMPLATE APPROACH.** Polymers exhibiting molecular recognition can be prepared by imprinting with templates. The selectivity observed is a result of the combination of the accuracy of cavity-shape fitting and the exactness of the arrangement of the functional groups introduced. We have now studied whether the arrangement of the functional groups alone can cause selectivity by virtue of the distinct distance between two such groups. By incorporation of polymerizable bisazomethines with different distances between the functional groups into crosslinked polymers and subsequent removal of the template, polymers bearing two amino groups fixed at a definite distance were obtained. In rebounding experiments with different dialdehydes the polymers showed a strong preference for the template used. The concept was broadened significantly by using for the first time a similar imprinting procedure on a silica surface through the formation of siloxane bonds. (Edited author abstract) 26 refs.

**082082 REAGENTS AND CATALYSTS DERIVED FROM POLYBENZIMIDAZOLE AND POLYSTYRENE RESINS WITH IMIDAZOLE PENDANT GROUPS.** Poly(benzimidazole) beads and similar reactive polymers containing benzimidazole groups attached to polystyrene resins have been used to prepare a variety of polymer-supported reagents and catalysts. For example, the polymers can be used to prepare supported palladium catalysts which are effective in the catalytic hydrogenation of nitro compounds or alkenes at room temperature. Poly(benzimidazole) has also been used to prepare a supported regenerable dichromate oxidizing agent. The great thermal stability of poly(benzimidazole)

can be used advantageously in other applications such as the gas-phase dehydrohalogenation of trichloroethane to vinylidene chloride. (Edited author abstract) 33 refs.

**082083 REACTIONS OF SUBSTRATES HYDROPHOBICALLY BOUND TO POLYMER SUPPORTS: STEREOCHEMICAL EFFECTS.** Reactions of substrates covalently bound to polymer supports usually proceed with essentially the same stereochemical result as non-supported reactions. However, reactions of substrates hydrophobically bound to polymer supports can produce substantially different stereochemical results from non-supported reactions. These effects are greatest when macroporous polymers with high internal surface areas are used, probably because the substrate molecules adsorb onto the internal surfaces of the polymers. (Author abstract)

**082084 MILD SYNTHESIS OF AZIDES BY MEANS OF A POLYMERIC REAGENT.** Organic azides are useful intermediates in the synthesis of pharmaceuticals, pesticides and photoaffinity labels. However, most methods leading to alkyl azides require either heating during their synthesis or purification by distillation, which is undesirable because of the thermal instability of these compounds. We have discovered a method that permits clean conversion of alkyl halides or sulfonates into alkyl azides by means of a polymeric reagent. The reaction proceeds under mild conditions at room temperature in a variety of solvents. The reaction can be monitored by GC or TLC. The polymer is removed by filtration and can be easily regenerated, and azide products are obtained cleanly without heating. Specific examples are discussed. (Author abstract)

**082085 ENANTIOSELECTIVE CATALYSIS BY POLYMER-SUPPORTED METAL PHOSPHINE COMPLEXES.** Because of the increasing demand for enantiomerically pure chemicals, the interest in methods for their preparation is growing. An elegant solution is offered by enantioselective catalysis, in which the chiral information is transferred from a very small to a very large amount of substrate. The academic interest manifests itself in the large number of homogeneous catalysts investigated, mainly based on chiral phosphine complexes. However, the difficulties in using such homogeneous noble-metal catalysts in industrial processes are well known. Homogeneous catalysts which are heterogenized by means of polymers are expected to contribute to overcoming these difficulties. The development of enantioselective catalysts of this type is reviewed. (Edited author abstract)

**082086 POLYMER SUPPORTED MICROORGANISMS AS BIOCATALYSTS.** Immobilization of microorganism on polymeric supports for bioreactions was first reported in 1959. Initiated additionally by a first attempt of ours in 1966 to entrap whole cells in polyacrylamide gels, a large number of immobilization methods was developed, and our laboratory contributed to this field in

a number of ways. Polymeric beads of different sizes and porosities can be prepared, and materials with other geometries such as membranes or solid and hollow fibers can be obtained as well. Mechanical and diffusional transport properties of such support materials can be determined in a quantitative way. With respect to the biocatalytic application of microorganisms, biotransformation and bioconversion reactions can be distinguished. (Edited author abstract)

**082087 GEL PHASE  $^{13}\text{C}$  NMR SPECTROSCOPY AS AN INVESTIGATIVE TOOL IN ULTRA-HIGH LOAD SOLID (GEL) PHASE PEPTIDE SYNTHESIS.** Solid (gel) phase peptide synthesis involves successive organic reactions on a matrix-peptide network. It is difficult to effect characterization at intermediate stages during the course of peptide assembly and so it can be difficult to obtain direct information on the status of hydrocarbon protecting groups, loading and de-loading phenomena, side reactions and their avoidance. The object of the present study has been to evaluate gel phase  $^{13}\text{C}$  NMR spectroscopy as a method for alleviating this problem. The method has been applied to determine the limiting stabilities of common acid-labile and base-labile N-terminal protecting groups in a reaction protocol which has been devised for use with phenolic supports. It has been possible to investigate concurrently the stability of the anchoring linkage under deprotection conditions. Valuable practical information has been obtained. (Edited author abstract)

Epton, Roger (Wolverhampton Polytechnic, Wolverhampton, Engl); Wellings, Donald A. *React Polym Ion Exch Sorbents* v 6 n 2-3 Oct 1987, Sel Pap Presented at the 3rd Int Conf on Polym-Supported React in Org Chem, Jerusalem, Isr, Jul 6-11 1986 p 333.

**082088 MATRIX EFFECT IN THE CATALYTIC ACTIVITY OF POLYMER-BOUND SULPHONIC ACIDS.** Polymer-supported acids and bases are widely employed as catalysts for organic reactions. However, very few systematic studies have been published on the influence of physical and chemical parameters on their catalytic activity. We have tackled this problem using polymeric sulfonic acids as catalysts. In order to study reactions in organic solvents, macroporous-type polymers with different surface areas were prepared. The catalytic activities of these polymer-supported acids were tested in electrophilic aromatic substitution reactions and rearrangement processes. In some cases a strong dependence of the catalyst efficiencies on the surface area of the polymer has been observed, but in other reactions this factor does not seem to be important. Studies on solvent effects in these reactions and on the interactions of the polymeric catalyst with Hammett bases have been performed. The results obtained, together with available data on similar systems, allow a molecular interpretation of the catalytic activity to be given. (Edited author abstract)

Arduini, A. (Univ of Parma, Parma, Italy); Pochini, A.; Ungaro, R. *React Polym Ion Exch Sorbents* v 6 n 2-3 Oct 1987, Sel Pap Presented at the 3rd Int Conf on Polym-Supported React in Org Chem, Jerusalem, Isr, Jul 6-11 1986 p 333-334.

**082089 SYNTHESIS, REACTIONS AND C-13 PFT-NMR SPECTROSCOPY OF POLYMER-BOUND STEROIDS.** The attachment of polymer-supported cholic acid derivatives with keto and hydroxy functionalities and the transformation of these groups are presented. Examination of the influence of the polymer support and spacer groups upon the stereochemistry of these reactions is discussed. In addition to the usual methods for analysis of polymer-bound reactions, C-13 PFT-NMR spectroscopy was employed to detect, on a qualitative basis, the changes in functional groups attached to the support. Limitations of the C-13 NMR spectral method are illustrated. (Edited author abstract)

Blossey, Erich C. (Oklahoma State Univ, Stillwater, OK, USA); Ford, Warren T.; Periyasamy, Mookkan; Mohanraj, S.; Cannon, Randall G. *React Polym Ion Exch Sorbents* v 6 n 2-3 Oct 1987, Sel Pap Presented at the 3rd Int Conf on Polym-Supported React in Org Chem, Jerusalem, Isr, Jul 6-11 1986 p 334.

**082090 SOLID-PHASE SYNTHESIS OF  $\alpha$ ,  $\omega$ -UNDECANEDIOL MONOMESYLATE.** Insect sex attractants by binding symmetrical  $\alpha$ ,  $\omega$ -diols to polymer supports, but the extent of double binding was substantial (ca.40%). We report an improved procedure. By optimization of reaction conditions, polymer-supported tritryl chloride was prepared with a capacity (up to 2.5 mmol/g) higher than obtained by previous workers. Polymer-supported  $\alpha$ -undecanediol monomesylate was then prepared. The procedure, which can be carried out efficiently, avoids double binding problems. (Author abstract)

Chen, Jiawei (Wuhan Teachers' Coll, Wuhan, China); Xu, Zhang-Huang; Li, Jianzong; Cheng, Shiyan. *React Polym Ion Exch Sorbents* v 6 n 2-3 Oct 1987, Sel Pap Presented at the 3rd Int Conf on Polym-Supported React in Org Chem, Jerusalem, Isr, Jul 6-11 1986 p 334.

**082091 PREPARATION OF A POLYMER-SUPPORTED HYDROXYTHIOL AND ITS REACTION WITH CARBONYL COMPOUNDS.** Polymer-supported diols have been used as protecting groups for aldehydes and ketones. We report the preparation of polymer-supported hydroxythiol. Polymer was prepared with a capacity of up to 2.5 mmol/g. Several dialdehydes and diketones were bound to polymer in loadings of 0.3-1.7 mmol/g. Various reactions, including Wittig reactions, were carried out on the free carbonyl groups of singly bound dicarbonyl compounds. After release from the polymer the ratio of Wittig product to starting material indicated that terephthalaldehyde was 70% single bound and 30% doubly bound. These results are similar to those obtained for polymer-supported acetals and ketals by other workers. (Edited author abstract)

**082092 STUDIES ON POLYMERIC REAGENTS. I. SYNTHESIS OF DICROCROCIS PUNCTIFERALIS GUENUEE, TRANS-10-HEXADECENE-1-AL, USING A POLYMERIC REAGENT.** cis-10-Hexadecene-1-ol was synthesized from polymer-bonded Wittig reagent. The sodium salt of  $\text{Me}_2\text{SO}$  in  $\text{Me}_2\text{SO}$  was used as base. Then, Dichrocrocis Punctiferalis Guenuee, trans-10-hexadecene-1-al, was synthesized after isomerization and oxidation. The structures of the product and intermediates were identified by IR,  $^1\text{H}$  NMR, MS and elemental analysis. The ratio of cis- to trans-10-hexadecene-1-ol before and after isomerization was determined as well. The results indicate that the above polymeric Wittig reaction has high cis-selectivity and that the ratio of cis- to trans-product corresponds with the requirement of biological activity of the sex pheromone. (Author abstract)

**082093 ENZYMIC PROCESS FOR THE PREPARATION OF D(+)-NAPROXEN.** D(+)-Naproxen [D-2-(6-methoxy-2-naphthyl)propionic acid] is well-known as an anti-inflammatory agent. We developed an enzymatic two-step process for obtaining D(+)-Naproxen from a mixture of D- and L-2-(6-methoxy-2-naphthyl)propionic acid lower alkyl esters by the asymmetric hydrolysis of the L-ester with microbial enzymes, separation of the L-acid from the D-alkyl ester and enzymatic saponification of the latter with esterase from hog liver and some other sources. Product yield is high and optical purity of the D(+)-Naproxen is 98%. The enzymes for this

process are preferably used as immobilized catalysts. Application of the enzymatic two-step process for technical production of D(+)-Naproxen seems feasible. We present data for: the L-specific enzymes; the immobilization of the enzymes and microorganisms used in this process; reactors in laboratory scale; and stability of the catalysts. **082094 FUNCTIONAL POLYMERS IN PHOTOGRAPHY.** This presentation is in two parts. In the first part, the broad significance of functional polymers in photography is discussed. Included are polymer science applied to supports, vehicles which may be natural (especially gelatin), synthetic, water-soluble or water-insoluble, mordants, timing layers, acid layers, and polymeric reagents. In the second part, a more in-depth treatment of polymers for the control of static electricity is presented. This includes a discussion of organic microgel polyionomers, both highly anionic and highly cationic, and an organic polyaniline semiconductor which, when sorbed to latex polymers, provides humidity-independent conductivity at exceptionally low surface coverages. (Edited author abstract)

**082095 OPTICALLY ACTIVE POLYMERS AS ADSORBENTS FOR DIRECT CHROMATOGRAPHIC RESOLUTION OF DRUGS.** Many chiral therapeutic agents are still used in therapy as racemates although enantiomers mostly differ in their pharmacological activities. In many cases, the reason is the difficulty of resolving the racemates via diastereoisomeric derivatives. Many of these racemates can be separated very efficiently by chromatography on optically active polymers such as polyamides. These polymers, having a wide range of applications, can be used repeatedly on an analytical as well as preparative scale without losing their resolution efficiency. Adsorbents for enantiomeric resolution can be obtained from natural polymeric products. Many examples for enantiomeric resolutions, especially of drugs, on an analytical as well as on a preparative scale are demonstrated. (Edited author abstract)

**082096 DIAGNOSTIC APPLICATIONS OF COMPARTMENTALIZED POLYMER REAGENTS.** In the past decade, a variety of homogeneous immunoassay methodologies have evolved in which the reactivity of an analyte-enzyme, analyte-cofactor, or analyte-inhibitor conjugate is modulated in the presence of a specific antibody. We describe an alternate approach in which enzymic reactivity is modulated by sequestering the enzyme within a liposome whose accessibility to substrates is increased by lysis in the presence of antibody and complement. This approach employs only two reagent formulations, does not require any sample pretreatment, and has high sensitivity. Therefore, it can be readily automated on random access clinical analyzers. (Edited author abstract)

**082097 INTRODUCTION OF PRIMARY HYDROXYL GROUPS INTO POLYMERS FOR IMPROVED AFFINITY CHROMATOGRAPHY AND PROTEIN IMMOBILIZATION.** Polymers containing hydroxyl groups such as polysaccharides are commonly used as carriers for affinity chromatography and protein immobilization after activation with appropriate reagents. We have recently shown that efficient activation of such polymers is achieved mainly through primary hydroxyl groups. This was indicated by the observation that the amount of active groups on the polymers correlates well with the amount of primary hydroxyl groups. It also made no difference whether the activation was performed with CNBr or with chloroformates. Since the activation was performed mainly on polysaccharides, there is a possibility that a vicinal hydroxy group interacts with the active group forming five-membered rings. Cheap and high-capacity columns are badly needed in industry in order to reduce the size of columns used for protein purification and immobilization. (Edited author abstract)

**082098 CHARACTERIZATION OF HUMAN INTERFERONS BY HPLC.** In recent years HPLC (high performance liquid chromatography) has become the preferred mode of protein isolation and characterization. Several types of HPLC sorbents based on various separation mechanisms were developed. These include gel permeation, hydrophobic interactions, polar interaction, ion exchange and chromatofocusing. Moreover, sorbent porosity was adjusted to allow efficient protein fractionations. Reversed-phase HPLC was employed for the isolation of human interferon as early as 1978. Recently, this method was used in an analytical mode to study the expression of individual subtypes of the interferon- $\alpha$  gene family. It was found that these genes are regulated individually. Moreover, different cells will express a different repertoire of subtypes. Interferon- $\gamma$ , which lacks any homology to interferons- $\alpha$  or - $\beta$ , is a product of a single gene. Nevertheless, post-translational processing yields a family of subtypes which can be resolved by cation exchange HPLC. These subtypes were found to differ in molecular weight and potency as antiviral and immunoregulatory agents. (Author abstract)

**082099 SOLID PHASE DERIVATIZATION APPROACHES FOR IMPROVED DETECTION IN HIGH PERFORMANCE LIQUID CHROMATOGRAPHY (HPLC).** Derivatizations for improved detection in high performance liquid chromatography have become more and more popular in the past few years. We describe here some of these newer, off-line and on-line, solid phase derivatizations for various classes of compounds, all of which have been developed in order to improve analyte selectivity and sensitivity in HPLC. Alkyl halides, epoxides, and related classes have been hard to detect by direct HPLC, but the use of an off-line, picric-acid-on-silica supported reagent has proven useful as a derivatization reagent. This has been used for tagging ethylene dibromide, leading to one or two picryl ether products. The analogous reaction has been shown for simpler alkyl monohalides, such as alkyl iodides, bromides, and chlorides. Application to biologically active amines or polyamines is in progress. (Edited author abstract)

**082100 POLYMERIC LIPOSOMES - ATTEMPTS**

**TO MIMIC BIOMEMBRANE PROCESSES.** The contribution deals with the stabilization of membrane model systems (monolayers, black lipid membranes, vesicles) in general. The desired further biological functionalization of these stabilized polymeric membranes is possible via incorporation of proteins. Addition of natural lipids to polymerizable membranes and enzymatic degradation of the unpolymerized component after polymerization makes selective opening of otherwise stable compartments possible. Cell-cell recognition - of vital importance in immunological reactions - can be mimicked with polymeric vesicles carrying sugar headgroups. Finally, attempts are made to unite biological specification of natural cells and toughness of polymerized membranes via cell-vesicle fusion. (Edited author abstract)

Ringsdorf, H. (Univ of Mainz, Mainz, West Ger). *React Polym Ion Exch Sorbents* v 6 n 2-3 Oct 1987, Sel Pap Presented at the 3rd Int Conf on Polym-Supported React in Org Chem, Jerusalem, Isr, Jul 6-11 1986 p 343.

**082101 REVERSIBLY POLYMERIZED LIPOSOMES.** Phospholipid bilayer vesicles are of considerable current interest as models for biomembranes, as carriers of drugs, and as devices for photochemical solar energy conversion. In this paper we describe two unique classes of synthetic vesicles which can be transformed into a polymerized state via oxidation and macrocyclic ring opening, respectively. These membranes are based on the thiol-bearing molecules, 1,2-bis(11-mercaptopentadecanoyl)-sn-glycero-3-phosphocholine, 1,2-bis(16-mercaptopentadecanoyl)-sn-glycero-3-phosphocholine, 1,2-bis(2-mercaptopentadecanoyl)-sn-glycero-3-phosphocholine, as well as a macrocyclic disulfide derivative of the first of these. Two key features of these assemblies, which distinguish them from other forms of polymerized phospholipid vesicles, are that they can be depolymerized via mild chemical reduction and that they are potentially biodegradable. (Author abstract)

**082104 SCALING THEORY OF CHROMATOGRAPHY OF LINEAR AND RING MACROMOLECULES.** Scaling concepts are used to obtain the distribution coefficients of linear and cyclic macromolecules in narrow pores in the GPC region. The distribution coefficients of self-nonintersecting linear chains and macrocycles in conditions of 'critical' chromatography are discussed. The authors also examine the problem of the behavior of self-non-intersecting linear and ring chains in conditions of so-called critical chromatography when the losses of the conformational entropy of the chain are compensated by the energy gain from the adsorption of the units on the pore walls. (Edited author abstract) 6 refs.

**082105 DETERMINATION OF FUNCTIONAL TYPE DISTRIBUTION OF OLIGOCAPROLACTONEDIOLS BY LIQUID CHROMATOGRAPHY UNDER CRITICAL CONDITIONS.** Functional type separation of oligocaprolactonedioles by liquid chromatography of macromolecules under critical conditions was investigated. The analysis was performed with the aid of a novel variant of HPLC in the critical region on the boundary of the exclusion and adsorption separation modes. This method is characterized by practically complete disappearance of separation by molecular masses thus giving only information on the type of functionality. The critical conditions have been found on two systems. The first consists of a Lichrospher Si 100 column and a hexane-acetone mixture as eluent, while the second consists of a Zorbax NH2 column and a diethylether-acetone mixture. (Author abstract) 3 refs.

**082106 HIGH-SPEED AND SUPER-SPEED SIZE-EXCLUSION CHROMATOGRAPHY OF POLYMERS FOR PROCESS ANALYSIS.** Super-speed high-performance liquid chromatography (HPLC) is becoming a popular analytical tool. Application of super-speed HPLC in process analysis may provide near real-time feedback control. Nonaqueous size exclusion chromatography (SEC) with silica-based stationary phase columns was studied in the high-speed and super-speed regimes. The dependency of solute resolution and chromatographic analysis time on experimental parameters, such as column back pressure, was investigated. A column selection procedure is proposed and applied by extrapolating information from the high-speed regime to the super-speed regime. (Edited author abstract) 18 refs.

**082107 POLYMER ADDITIVE CHARACTERIZATION BY CAPILLARY SUPERCRITICAL FLUID CHROMATOGRAPHY/FOURIER TRANSFORM INFRARED MICROSCOPY.** High-resolution capillary supercritical fluid chromatography (SFC) is shown to be an efficient separation technique for the qualitative analysis of chemical additives in polymers. Twenty-one compounds varying in chemical composition and molecular mass from 225 to 1178 are separated on a nonpolar capillary column by using carbon dioxide as the mobile phase. A polypropylene extract is analyzed to exemplify the method and highlight the limitation of using retention time data for identifying unknown compounds. The use of Fourier transform infrared spectrometry

(FTIR) as a detector provides unique spectroscopic information for identification purposes. (Edited author abstract) 23 refs.

**082108 UNIVERSAL CALIBRATION IN EXCLUSION CHROMATOGRAPHY OF POLYVINYLPIRROLIDONE IN DIMETHYL FORMAMIDE.** A universal calibration relation is obtained for the chromatographic separation of PVP and PS in DMFA on Microsyrigel columns of pore size  $10^3$ ,  $10^4$ , and  $10^5$  Angstrom. The proposed chromatographic system was used to analyze high dispersion grade NBS 706 PS, narrow dispersion grade NBS 705 PS, and wide dispersion PVP, the characteristics of which were determined by independent methods. The data from the analysis are given. The good correspondence between the molecular characteristics as found independently with those calculated by means of UCR is a good indication that UCR are useful for application to PVP and PS. (Edited author abstract) 24 refs.

Boimirzayev, A.S. (USSR Acad of Sciences, USSR); Nesterov, V.V.; Belenkii, B.G. *Polym Sci USSR* v 23 n 12 Dec 1987 p 2920-2923.

**082109 DYNAMIC HEADSPACE ENRICHMENT/REINJECTION FOR OPEN TUBULAR GC/FTIR ANALYSIS OF VOLATILES IN POLYMERS.** An analytical system for the analysis of volatiles entrained in polymers is described. This system is based on a thermal desorption oven connected to a cold trap. After enrichment of headspace vapor, trapped material is reinjected and analyzed by open tubular gas chromatography/Fourier transform infrared spectroscopy, OTGC/FTIR. The thermal desorption oven is designed to provide different modes of sample introduction: use of a pyroprobe; insertion of a piece of quartz tubing with applied sample; or syringe injection. **082110 THERMODYNAMIC STUDIES ON POLY[N-(n-OCTADECYL)MALEIMIDE] (PMI-18)/SOLVENT SYSTEMS BY INVERSE GAS CHROMATOGRAPHY WITH CAPILLARY COLUMNS.** An open tubular column (capillary) coated with poly[N-(n-octadecyl)maleimide] (PMI-18) has been used above its glass transition temperature for estimating polymer-solvent interaction parameters by means of inverse gas chromatography (IGC). Experimental retention volumes corrected to zero flow rate  $V_g^0$  are reported for nonpolar and polar solute probes. Activity coefficients ( $a_1/\omega_1$ ), the Flory-Huggins parameter  $\chi$ , and mixing functions were derived and discussed with respect to the chain length and polarity in the solute molecules. (Edited author abstract) 56 refs.

Barrales-Rienda, J.M. (CSIC Juan de la Cierva, Madrid, Spain); Gancedo, J. Vidal. *Macromolecules* v 21 n 1 Jan 1988 p 220-228.

**082111 RESOLUTION OF ELECTROSTATIC AND STERIC FACTORS IN AQUEOUS SIZE EXCLUSION CHROMATOGRAPHY.** Size exclusion chromatography of sodium poly(styrenesulfonate) (NaPSS) on CPG porous glass has been studied in order to elucidate the influence of intermacrolon expansion and polyion-stationary phase interaction on elution behavior. Measurement of the diminution of the chromatographic partition coefficient,  $K'_{SEC}$ , for the polyion, relative to that of a nonionic polymer (pullulan) of identical molecular volume makes it possible to isolate the contribution of polyion-substrate repulsive forces to  $K'_{SEC}$ . This effect may be approximately attributed to a volume within the pore from which the polyion is repelled. (Edited author abstract) 31 refs.

**082112 STUDY OF ACCEPTOR-DONOR INTERACTIONS AT THE POLYMER INTERFACE BY INVERSE GAS CHROMATOGRAPHY DATA ANALYSIS.** Analysis of inverse gas chromatography (IGC) data supports Fowkes's theory of acceptor-donor (acid-base) interactions at the polymer interface. Moreover, this analysis allows one to estimate Drago parameters of some polymers and IGC probes. The Drago parameters of copolymers of vinyl acetate and vinyl alcohol were found to vary linearly with copolymer composition. (Edited author abstract) 10 refs.

Chen, Fute (Univ of Illinois at Urbana-Champaign, Urbana, IL, USA). *Macromolecules* v 21 n 6 Jun 1988 p 1640-1643.

**082113 ANALYSIS OF WATER-SOLUBLE POLYMERS USING HYDRODYNAMIC CHROMATOGRAPHY.** Hydrodynamic chromatography (HDC) has been successfully applied to measurements of the molecular size and molecular size distribution of high molecular weight, water-soluble polymers. The scope of the method has been probed by experiments with xanthan, a comparatively stiff polysaccharide, and hydrolyzed polyacrylamide, which possesses a more flexible backbone. Separation occurs during convection of dissolved polymer through the interstitial volume of a chromatography column packed with nonporous beads. Nonequilibrium polymer configurations are readily created by the complex flow between these beads. Such altered configurations strongly affect molecular size measurements. (Edited author abstract). 39 Refs.

**082117 DETERMINATION OF REACTIVE COMONOMERS AND/OR AMINO RESINS IN ACRYLIC COPOLYMERS USED IN TEXTILE INDUSTRY, BY PYROLYSIS-GAS CHROMATOGRAPHY-MASS SPECTROMETRY.** Acrylic copolymers are used in the textile industry as binders for nonwoven fabrics, pigment printing or finishing. These binders must stabilize the fabrics during treatments such as washing and dry cleaning. For this purpose self-crosslinking acrylic copolymers or mixtures of acrylic copolymers and amino resins are often used. In this work, a method has been developed to determine whether reactive acrylic comonomer and/or amino resin are present in the acrylic copolymers. The technique applied, based on coupled pyrolysis-gas chromatography-mass spectrometry, can be used to separate and identify all the pyrolysis products of the polymer. (Author abstract) 23 refs.

## Cleaning

**082118 REMOVAL OF TRIGLYCERIDES FROM POLYMER SURFACES IN RELATION TO SURFACTANT PACKING. ELLIPSOMETRY STUDIES.** The removal of triglycerides from polymer surfaces by surfactant mixtures and by surfactants combined with inorganic salts or organic solvents has been studied by ellipsometry. Important results are that the efficiency of ionic surfactants can be enhanced by addition of inorganic salts and that the efficiency of ionic surfactants can be enhanced by addition of hydrocarbons. The removal process starts with the adsorption and aggregation of surfactant molecules at the soil/water interface. This aggregation is affected by the geometric properties of the surfactant molecules in the aggregates, such as head group area, hydrocarbon chain length, and volume. It is postulated that maximal removal is related to the packing of the surfactant molecules. The optimal packing is obtained in planar layers, i.e., zero curvature toward water and soil. The results show that a decrease in curvature corresponds to an increase in the soil removal, and can predict the detergency of surfactant solutions. (Edited author abstract). 49 Refs.

## Coagulation

**082119 PREPARATION OF COMPOSITE FINE PARTICLES BY HETEROCOAGULATION.** To prepare regular composite particles comprised of organic and inorganic compounds, based on heterocoagulation theory, the properties of the mixture of small amphoteric latices and large spherical silica were investigated as a function of pH, particle number ratio, particle size ratio, particle size ratio and electrolyte concentration in the medium. It is apparent that under suitable conditions, we may prepare a stable mixed suspension comprising uniform composite particles, which are made up of many latices regularly adsorbed on silica surfaces, and each composite particle is undergoing Brownian motion as an isolated unit. This new composite particle is very stable for electrolyte, base and acid medium, and its surface charges (sign and magnitude) can be controlled by changing the pH of the medium. (Edited author abstract) 7 refs.

## Coatings

**082120 POLYMER COATINGS WITH A DESTABILIZING ACTION ON SUSPENSIONS.** The rheological behavior of concentrated suspensions of spherical glass particles can be influenced drastically by surface pretreatment of the particles. This treatment consisted of silanization with mono- or difunctional organo-silicon compounds. Results from ESCA, IR and SEM analysis strongly suggest that silanization with the reagent dimethyldichlorosilane (DMDCS) results in a more or less homogeneous layer of oligomer and/or polymer depending on the processing. The particles were suspended in an apolar liquid (DOP) and in a polar liquid (glycerol/water). All suspensions exhibited perfect or nearly Newtonian behavior except DMDCS-coated glass in glycerol/water. (Edited author abstract) 17 refs.

**082122 POLYMER COMBUSTION: A REVIEW.** The study of polymer combustion is important first to the use of polymers as fuel binders in composite solid propellants and secondly to the understanding of polymer flammability so that fire retardants can be developed effectively. Polymer combustion is mainly associated with two phenomena, viz.: ignition and burning. This review aims at giving a complete picture of the process of polymer combustion. This paper covers the process of polymer combustion, specifically the reactions occurring in the condensed and gas phases. Some of the topics discussed are combustion chemistry, thermal degradation, oxidative degradation, surface reactions, oxygen index, smoke evolution, and smoke abatement. 129 refs.

**082123 ROLE OF PYROLYSIS IN POLYMER COMBUSTION AND FLAME RETARDANCE.** The authors conducted thermoanalytical studies of polymer pyrolysis in the absence and presence of oxygen; and, in particular, the behavior observed with polymer-flame retardant systems can provide valuable information about the complex physical and chemical interactions which may take place between the polymers and additives. Examples are given showing how the effects of certain bromine, phosphorus and metal compounds on polymer combustion can be interpreted in the light of the thermoanalytical behavior of mixtures of these compounds with selected polymers. Finally it is pointed out that studies of the controlled pyrolysis of polymers and polymer-flame retardant systems using conventional thermoanalytical equipment may have only limited relevance to the combustion of these same materials, since the total heat fluxes involved are so much greater during combustion than in thermal analysis. ## Compounding See Also PLASTICS; POLYMERIZATION.

**082125 TWIN-SCREW COMPOUNDING.** In the U.S. plastics industry, there is a growing trend toward the modification of polymers as a way of improving their physical properties and cost competitiveness. A wide variety of additives are available to reduce or eliminate the various types of degradation (thermal, mechanical, chemical, environmental). The availability of improved processing equipment has had a major influence on the type and levels of additives used today. The improved dispersion obtained with multiscrew extruders has actually allowed a reduction in the amount of additives required. This lowers additive costs and in many cases results in improved physical and processing properties. The author examines: continuous compounding, twin screw compounding; commercial compounding requirements; fiber reinforcing; fillers; color concentrates; alloying; liquid injection; and, two-stage compounding systems.

**082126 DEVELOPMENT OF DISPERSION IN THE MIXING OF CALCIUM CARBONATE INTO POLYMER BLENDS IN AN INTERNAL MIXER.** An experimental study of agglomeration tendency and the compounding of calcium carbonates of varying particle size into polypropylene and polystyrene melts in an internal mixer and in a two roll mill is described. The tendency of particles to agglomerate was studied using the sedimentation volume method. Agglomeration increased with decreasing particle size. It was sharply reduced by coating with stearic acid. Agglomerate size distributions in thermoplastic matrices were measured using optical microscopy. Stearic acid coating reduced the number of large agglomerates. (Edited author abstract) 16 refs.

## Compressibility

**082128 INFLUENCE OF HYDROSTATIC PRESSURE ON MOLECULAR DYNAMICS IN POLYMERS. REVIEW.** The patterns of segmental dynamics of macromolecules and the dynamics of low molecular weight particles on volumetric compression of solid polymers are discussed. Experimental evidence indicates that the view long prevalent on the different scale of the kinetic elements involved in the  $\alpha$  and  $\beta$  processes (dipole-segmental and dipole-radical) has not been confirmed. It has been established that the existence of these processes is a common property of amorphous substances, both polymers and liquids, including rigid ones without internal rotations of the molecules. It was also found that the ratio of the charges released in the  $\alpha$  and  $\beta$  processes on thermal disruption of polarization brought about in the polymer by a constant electric field concurs with the ratio of the activation volumes of these processes. 62 refs.

## Computer Simulation

**082129 MOLECULAR MODELING OF POLYMERS - II. ESTIMATION OF MELT TRANSITION TEMPERATURES.** Computer-aided molecular modeling methods are presented to estimate the melt transition temperature,  $T_m$ 's, of polymers in solution and in the crystalline state. A calibration-based melt transition model can be used on a congeneric series of polymers where at least one known  $T_m$  is available to scale the computation. This model is applied to a set of collagen triple-helix tripeptide and hexapeptide analogs, and to four classes of crystalline synthetic polymers. (Edited author abstract) 24 refs.

**082130 MOLECULAR DYNAMICS OF A MODEL POLYMER ON A HYPERCUBE PARALLEL COMPUTER.** In this paper, we discuss the implementation and solution of molecular dynamics polymer models on the Intel iPSC Hypercube parallel computer. We first describe a model problem whose inherent parallelism can be exploited effectively and which is therefore amenable to parallel solution. We next discuss the salient features of the hypercube programs that were used to solve the model problem. Finally, we present results which demonstrate that the efficiencies of the solutions approach 100% as the number of atoms in the polymer and the number of hypercube processors are increased for the problem in question. The results demonstrate that parallel solutions of polymer problems using a hypercube architecture offer potentially significant savings over sequential solutions. (Author abstract) 25 refs.

**082131 MODELING OF NETWORK SYSTEMS.** This study deals with polymers which react by a stepwise reaction. Properties such as cross-link density, which rely on the reactivity of the functionalities and types of chemical bonds formed by the cross-linking of the monomers, have been modeled. Computer modeling is employed to predict the number of functionalities reacted on each multifunctional monomer, cross-link density, and reactivity of functionalities in the cross-linked system. The computer model calculates data from networks formed by a stepwise reaction and includes corrections for substitution effects. The polymer used to illustrate the model is the network formed by the tetrafunctional epoxy, tetra-

glycidyl(diaminodiphenyl)methane, and the tetrafunctional amine, diaminodiphenyl sulfone. (Edited author abstract) 43 refs.

**082133 ANTIPLASTICIZATION AND VOLUMETRIC BEHAVIOR IN GLASSY POLYMERS.** A model is proposed for understanding changes in the volumetric and the free-volume properties of a glassy polymer upon addition of a low molecular weight diluent. The proposed theory for volumetric behavior appears to describe the negative departures from volume additivity that have been observed experimentally in glassy polymer-diluent systems. An expression is derived for the concentration dependence of the specific hole free volume in a glassy polymer-diluent mixture. This expression is used to explain antiplasticization behavior in glassy polymers and to rank the antiplasticization effectiveness of various diluents that are added to a particular polymer glass. (Author abstract) 15 refs.

**082134 SYNTHESIS AND CHARACTERIZATION OF ABA BLOCK COPOLYMER-BASED POLYMER ELECTROLYTES.** The synthesis and some of the properties of a novel ion-conducting polymer are described. The polymer, based on a styrene-butadiene-styrene ABA triblock copolymer has pendant, short-chain poly(ethylene oxide) (PEO) grafted onto the B block. The concentration of PEO in the polymer can be controlled by varying either the number of pendant groups per molecule or the molecular weight of the PEO chain. The polymers were combined with  $\text{LiCF}_3\text{SO}_3$  to form ion-conducting phases. The conductivities of films of these materials were found to be sensitive to preparation technique, and especially to casting solvent. The temperature dependence of the conductivity suggested that the materials were essentially amorphous over the range studied. (Edited author abstract) 25 refs.

Giles, J.R.M. (Royal Aircraft Establishment, Farnborough, Engl); Gray, F.M.; MacCallum, J.R.; Vincent, C.A. *Polymer* v 28 n 11 Oct 1987 p 1977-1981.

**082135 THIOPHENE ELECTROPOLYMERIZATION BY CYCLIC VOLTAMMETRY: TEMPERATURE INFLUENCE.** The influence of temperature on the thiophene oxidation-polymerization was studied by

cyclic voltammetry. The temperature increase up to 15-20°C promotes a faster surface polymerization. At higher temperatures the formation and growth of the polymer layer is slower due to the lower conductivity of the polymer layer formed at the first potential cycle. This decrease in polymer conductivity may be related to the increase of mobility of the monomer ion radicals (formed by monomer oxidation) in the diffusion layer, as shown by a rotating disk electrode. (Author abstract) 15 refs.

Otero, Toribio Fernandez (Basque Country Univ, San Sebastian, Spain); de Larreta-Azelain, Enrique. *Polym Commun (Guildford Engl)* v 29 n 1 Jan 1988 p 21-24.

**082136 GRAFTING OF POLY( $\alpha$ -CHLOROACRYLONITRILE) ( $\alpha$ -PCIAN) ON CARBON BLACK AND ELECTRICAL PROPERTIES OF  $\alpha$ -PCIAN-GRAFTED CARBON BLACK COMPOSITIONS.** The electrical properties of poly( $\alpha$ -chloroacrylonitrile) (PCIAN) carbon black compositions were determined. These materials were prepared by polymerizing  $\alpha$ -chloroacrylonitrile in the presence of carbon black (GC resistors). Resistivity measurement of GC resistors shows a semiconductor-like behavior. Moreover, the resistance change of GC resistors with electrical field strength is very large. It is concluded that the conduction of GC resistors is controlled by the thin polymer layer present at the surface of the carbon black particles. Heat degradation of such compositions was also investigated. (Edited author abstract) 7 refs.

Miyauchi, Shin'Nosuke (Technological Univ of Nagaoka, Nagaoka, Jpn); Mino, Nobuhiro; Balard, Henri; Papirer, Eugene; Donnet, Jean Baptiste. *J Appl Polym Sci* v 35 n 1 Jan 1988 p 127-134.

**082137 CHAIN RIGIDITY-PROCESSABILITY CORRELATION IN INHERENTLY CONDUCTING POLYMERS.** The author investigated the problem of how to introduce processability into conducting polymeric materials while preserving their conjugated character. The author focused on one approach to achieve such progress, which is the use of Lewis acid coupling reactions and an extensive characterization to understand the materials properties. It can be concluded that a certain degree of crystallinity is needed to achieve high conductivities. Since it is quite possible that the spin localization is due to the presence of a large amount of arsenic, it might be of interest to use other catalytic systems such as  $\text{SbF}_3/\text{SbF}_5$ ,  $\text{SO}_3/\text{H}_2\text{SO}_4$ ,  $\text{BF}_3/\text{HBF}_4$ ,  $\text{PF}_5/\text{HPF}_6$ , etc. as solvent/catalyst couples. 26 refs.

Aldissi, M. (Los Alamos Natl Lab, Los Alamos, NM, USA). *Polym Plast Technol Eng* v 26 n 1 Mar 1987 p 45-70.

**082138 STUDY OF POLYPYRROLE SYNTHESIZED WITH OXIDATIVE TRANSITION METAL IONS.** Polypyrrole powder and films were chemically synthesized by the reaction of  $\text{AgNO}_3$ ,  $\text{FeCl}_3$ ,  $\text{Fe}(\text{NO}_3)_3$ ,  $\text{Cu}(\text{NO}_3)_2$ , or  $\text{Cu}(\text{NO}_3)_2\cdot\text{AlCl}_3$  with pyrrole in an aqueous solution or a water-toluene two-phase system. Products were characterized by elemental analysis, IR, scanning electron microscopy with energy dispersive x-ray analysis (SEM with EDAX), and conductivity measurements. The polypyrrole synthesized from pyrrole with  $\text{FeCl}_3$  had a composition of  $\text{C}_{4.00}\text{H}_{3.05}\text{N}_{0.99}\text{Cl}_{0.25}$ . All the other metal salts produced films that had the same organic backbone, morphology, and conductivity as the polymer synthesized using  $\text{Fe}(\text{III})$  salts, regardless of the considerable differences in the reduction potentials of the metal ions. The nature of the anions of the transition metal salts had no effect on the reaction. (Edited author abstract) 10 refs.

Chao, Taina H. (SUNY Purchase, Purchase, NY, USA); March, Juan. *J Polym Sci Part A* v 26 n 3 Mar 1988 p 743-753.

**082139 STUDIES ON SOME PROPERTIES OF PRISTINE AND IODINE-DOPED POLY(PHENYLENE SULPHIDE).** Some properties of poly(phenylene sulphide) prepared by direct synthesis from benzene and sulphur are discussed in the light of thermal analysis,

X-ray, SEM, and infrared data. Pristine poly(phenylene sulphide) is characterized by large thermal stability; it loses only 22.5% of its mass during dynamic heating to 873 K. Mass loss for iodine-doped samples increases to 41% depending on the iodine content. Doping with iodine also changes crystallinity and morphology and brings about a rise of electrical conductivity by several orders of magnitude. A conductivity of  $1.45 \times 10^{-2} \text{ S m}^{-1}$  was obtained in air at room temperature for the sample containing 22.6% iodine. (Author abstract) 12 refs.

Kreja, Ludwik (N. Copernicus Univ, Torun, Pol); Warszawski, Andrezej. *J Mater Sci* v 23 n 2 Feb 1988 p 497-500.

**082140 ELECTROCHEMICAL DOPING REACTIONS OF THE CONDUCTING LADDER POLYMER BENZIMIDAZOBENZOPHENANTHROLINE (BBL).** The electrochemical reactivity of films of the polymer is examined by using cyclic voltammetry, coulometry, and spectroelectrochemistry. In contact with acidic aqueous ( $\text{Bu}_4\text{N})_2\text{SO}_4$  buffer, BBL voltammetry exhibits two redox steps corresponding to the sequential reduction of the unprotonated and the protonated forms of BBL connected by a  $\text{pK}_a = 2.2$ . The reductions consume overall one electron and one proton per BBL monomer site. The (more positive) reduction of unprotonated BBL is proposed to involve protonation at the carbonyl to yield a quinone/hydroquinone form; reduction of the protonated BBL is proposed to involve protonation of imine sites to yield a quinone/quinimine form of the polymer. The quinone/quinimine form is the more electrically conductive form of doped BBL. (Author abstract) 10 refs.

**082141 NEW CHEMICALLY PREPARED CONDUCTING 'PYRROLE BLACKS'.** A series of electrically conducting pyrrole 'black' polymers has been prepared by chemical oxidation of pyrrole with a variety of ferric salts. The synthesis and properties of these materials are described and compared with electrochemically-prepared analogs. Pyrrole 'blacks' with strong acid anion 'dopants' exhibited the highest conductivities, up to  $62 \Omega \text{ cm}^{-1}$  for the triflate-doped polymer. The adjustability and ease of synthesis of the ferric-derived polypyrroles render these particularly promising for large-scale processing of conducting polymers. (Author abstract) 17 refs.

Walker, John A. (Rockwell Int Science Cent, Thousand Oaks, CA, USA); Warren, L.F.; Witucki, E.F. *J Polym Sci Part A* v 26 n 5 May 1988 p 1285-1294.

**082142 OPTICAL PROPERTIES OF CONDUCTING POLYMERS.** In this review the authors have summarized the optical studies of some of the key conducting organic polymers that have become important in recent years. Conducting polymers can be broadly divided into two types, namely, those with a degenerate ground state and solitons as the important excitations and those where the ground-state degeneracy is lifted so that polarons and bipolarons are the important excitations and the dominant charge-storage configurations. Polyacetylene,  $(\text{CH})_n$ , is the extensively studied example with a degenerate ground state (the double and single bonds can be interchanged with no cost of energy). Poly(p-phenylene), poly(p-phenylene sulfide), and polyheterocycles (polypyrrole, polythiophene, etc.) each have a nondegenerate ground state (for example, in poly(p-phenylene) the quinoid form has a higher energy than the benzenoid form). 68 refs.

Patil, A.O. (Univ of California, Santa Barbara, CA, USA); Heeger, A.J.; Wudl, F. *Chem Rev* v 88 n 1 Jan-Feb 1988 p 183-200.

**082143 PERCOLATION PHENOMENA IN POLYMER/CARBON COMPOSITES.** Samples of polyester, polyvinylchloride or polycarbonate with various amounts

of carbon black were studied. Percolation phenomena in electrical and dielectric properties have been systematically studied. Critical exponents from the resistivity of conductive samples ( $t=1.9$ ) and the dielectric constant of insulative samples ( $s=0.8$ ) agree well with theoretical predictions (2.0 and 0.7, respectively) and experimental values (2.0 and 0.7, respectively from inorganic composites). Critical behavior in the loss factor of insulative samples has also been demonstrated for the first time. Factors affecting the percolation threshold are briefly discussed. 25 refs.

Hsu, William Y. (DuPont, Wilmington, DE, USA); Holtje, Wilfried G.; Barkley, John R. *J Mater Sci Lett* v 7 n 5 May 1988 p 459-462.

**082144 ELECTRICAL AND THERMAL STABILITY OF CHEMICALLY SYNTHESIZED CONDUCTIVE POLYPYRROLE-HALOGEN COMPLEXES.** Conductive polypyrrole (PPY)-halogen complexes were obtained via the simultaneous chemical polymerization and oxidation of pyrrole by bromine ( $\text{Br}_2$ ), iodine ( $\text{I}_2$ ) or chlorine ( $\text{Cl}_2$ ). The thermal stability of these complexes was studied by thermogravimetry while the electrical stability was characterized by electrical conductivity measurements at various temperatures and current loadings, as by cyclic voltammetry. Although the PPY- $\text{I}_2$  complex shows the best thermal-physical stability, the PPY- $\text{Br}_2$  complex has the most favorable electrical properties. The room temperature electrical conductivity of the PPY- $\text{Br}_2$  complex is about 33 S/cm and the complex can sustain a current density of at least 6 A/cm<sup>2</sup> for more than 100 h without any degradation in conductivity. The weight and electrical conductivity of the sample, however, decrease when heated above 140°C. Both the PPY- $\text{I}_2$  and PPY- $\text{Br}_2$  complexes show good stability upon repeated redox cycling in both aqueous and organic electrolytes. (Author abstract). 18 Refs.

Neoh, K.G. (Nat'l Univ of Singapore, Kent Ridge, Singapore); Kang, E.T.; Tan, T.C. *Polym Degradation Stab* v 21 n 2 1988 p 93-103.

**082145 ESCA ANALYSIS OF POLYMER-ACCEPTOR INTERACTIONS IN CHEMICALLY SYNTHESIZED POLYPYRROLE-HALOGEN COMPLEXES.** X-Ray photoelectron spectroscopy (XPS) studies have been performed on conductive polypyrrole (PPY)-halogen complexes, such as PPY- $\text{I}_2$ , PPY- $\text{Br}_2$ , and PPY- $\text{Cl}_2$  complexes, prepared by the simultaneous chemical polymerization and oxidation of pyrrole by the respective halogens. Substantial halogenation of the pyrrole ring was observed in the case of PPY- $\text{Cl}_2$  and PPY- $\text{Br}_2$  complexes. In the case of PPY- $\text{Br}_2$  complex, the ratio of covalent to ionic bromide content can be effectively varied over a wide range by varying the bromine to monomer ratio used for polymerization. The increase in covalent bromide content causes a decrease in the electrical conductivity of the complex. (Edited author abstract). 22 Refs.

**082146 MAGNETIC SUSCEPTIBILITY OF POLYPYRROLE AND POLYTHIOPHENE CONDUCTING POLYMERS.** Conducting polymers have been a subject of great interest almost for a decade due to their outstanding electronic properties. A wide variety of electrically conducting polymers exhibiting nearly conductivity of metallic type have been investigated. The electrical behavior of these polymers is strongly influenced by the presence of counter-anion, solvents etc., in the conducting state. Apart from their conducting properties, these polymers should also exhibit interesting magnetic properties since dynamic defects formed during the electrooxidation polymerization are intrinsic to the polymer. The ESR measurements have been conducted on polythiophene and polypyrrole in order to study the conduction mechanism. 34 Refs.

**082148 ORGANIC CONDUCTORS.** Scientists from many disciplines are now combining expertise to study organic solids that exhibit remarkable conductivity properties. Organic chemistry, X-ray crystallography, solid state physics, material science and microelectronic engineering have found a unique meeting ground. These novel materials, which may be crystalline or polymeric, have the advantage that they are structurally versatile and potentially cheaper and easier to fabricate than the traditional inorganic conductors - but the industrial success of conducting organic materials may well depend on the ingenuity of the synthetic organic chemists as they learn to become molecular engineers. Subtle variations in the chemical structure of molecules can regulate the bulk electrical, optical or magnetic properties of the material. 14 Refs.

Bryce, Martin R. (Univ of Durham, Durham, Engl). *Chem Br* v 24 n 8 Aug 1988 p 781-785.

**082149 SYNTHESIS AND ANALYSIS OF SOME SULPHUR AND NITROGEN CONTAINING CONDUCTING POLYMERS INCLUDING CONDUCTING POLYMER BLENDS OF POLY(3-OCTYLTHIOPHENE).** This thesis deals with inherently conducting polymers and has been divided into two parts. The first part deals with the synthesis, characterization and electrical conductivities of the derivatives of poly(p-phenylene sulfide) and poly(p-azophenylene), poly(2,4-azotoluene), poly(ethylene vinylene sulfide), poly(2,6-pyridine), poly(2,6-pyridine sulfide), poly(3,6-pyridazine) and poly(3,6-pyridazine sulfide). Undoped polymers are insulators (conductivity  $<10^{-8}$  S/cm) but during doping the conductivities rise as high as  $10^{-3}$  S/cm. The doped polymers were studied using IR and ESR spectrometry. The second part describes the preparation of poly(3-octylthiophene) (POT) and the polymer blends of it. POT is solution and melt processable and when doped with iodine the conductivity rises to 20 S/cm. POT has been hot pressed onto a polymer substrate which after doping has a conductivity of 20 S/m blended and blow molded with different processable polymers (PE, PP, EVA, EBA). When doped the conductivities of the blends are 1 S/cm. Blends of this type might be useful in applications such as electromagnetic interference (EMI) shielding, electrostatic discharge (ESD) elimination and semiconducting layers in high voltage cables. (Edited author abstract). 99 Refs.

**082150 CONDUCTION MECHANISM OF POLYANILINE: EFFECT OF MOISTURE.** It has recently been shown that the emeraldine base polymer form of polyaniline undergoes a transition from an insulating to a metallic state upon protonation with HCl. The conductivity of the protonated polymer is sensitive to the moisture content of the polymer, varying by as much as a factor of five upon pumping the samples. The authors report the temperature-dependent microwave frequency ( $10^{10}$  Hz) conductivity and dielectric constant as a function of environmental history. The results are consistent with the effect of moisture on the barriers between small metallic polymer grains. Texture of granular metal particles and localization within metallic islands are decisive in the frequency- and temperature-dependence of the conductivity and dielectric constant. (Author abstract). 35 Refs.

**082151 ELECTROCHEMICAL BEHAVIOUR OF POLYPYRIDAZINE AND o-, m-, p-DIAZINES.** The electrochemical behaviors of polypyridazine (PPd), an electrically conducting polymer, its monomer pyridazine, and isomers pyrazine and pyrimidine, have been studied by cyclic voltammetry. When the electrochemical behaviors of the three diazines in acetonitrile (MeCN) solution with different supporting electrolytes (such as  $\text{LiClO}_4$ ,  $\text{NH}_4\text{BF}_4$ ,  $\text{KPF}_6$ ,  $\text{KAsF}_6$ ) are compared, it is found that under each of the above conditions the oxidation peak potential of pyridazine is the lowest, but its peak current is the highest. When  $\text{LiClO}_4$  or  $\text{NH}_4\text{BF}_4$  is used as the supporting electrolyte, pyridazine can be polymerized to form a dark greenish-blue PPd film on the anode, while pyrimidine or pyrazine is oxidized only to produce a yellowish powdery precipitate. (Edited author abstract). 9 Refs.

**082152 ELECTROCHEMICAL COPOLYMERIZATION OF BENZO[b]THIOPHENE.** Many attempts have been made to produce new conducting polymers such as polypyrrole, polythiophene and polyaniline by electrochemical polymerization. This paper reports on the electrochemical copolymerization of benzo[b]thiophene with pyrrole and the conditions for producing flexible and transparent conductive films. Highly conducting polymer films that are stable to ambient conditions and have good mechanical properties can be obtained by the electrochemical copolymerization of benzo[b]thiophene with pyrrole if a suitable supporting electrolyte, solvent, current density and copolymer composition are selected. (Edited author abstract). 7 Refs.

**082153 PHOTOINDUCED LOCALIZED CHARGED EXCITATIONS IN POLYANILINE.** The authors report the infrared photoinduced absorption spectra of polyaniline in the 'emeraldine' base form while pumping into the two optical transitions at 2.0 eV and 4.0 eV, respectively. For optical pumping at energies near 2.0 eV, they found photoinduced infrared-active vibrational (IRAV) modes that are essentially identical to those observed subsequent to protonation. They propose that the optical absorption at 2.0 eV in the emeraldine form is due to an  $n-\pi^*$  transition from the non-bonding nitrogen lone-pair to the conduction ( $\pi^*$ ) band. With 4.0 eV optical pumping, the IRAV modes are significantly different, demonstrating that a different species is produced when pumping into the  $\pi-\pi^*$  transition. The analysis, based on the amplitude mode formalism, indicates that the charged photoexcitations and the polarons that are generated through protonation are localized and not highly mobile. (Author abstract). 16 Refs.

**082154 IMPROVEMENT IN THE QUALITY OF POLYPYRROLE FILMS PREPARED ELECTROCHEMICALLY ON A MERCURY ANODE.** The synthesis and some properties of polypyrrole formed on a mercury anode are described. Conductivity values in the range 40-90 S/cm compare favorably with those of films produced on other electrodes. Use of the p-toluenesulfonate anion at a concentration of 0.3 M, pH of 4.8, and a temperature of 0°C led to the best conductivity observed

in free-standing films produced on a mercury anode. A maximum thickness of about 280  $\mu\text{m}$  was achieved under optimum conditions. (Author abstract). 12 Refs.

**082155 ELECTROCHEMICAL CONTROL OF THE MORPHOLOGY, ADHERENCE, APPEARANCE AND GROWTH OF POLYPYRROLE FILMS.** The influence of the electrochemical method employed to electrogenerate polymer films on morphology, appearance and adherence to a platinum electrode was studied. The use of a potential step or cyclic voltammetry and square waves of potential at different frequencies, respectively, allows one to obtain a dendritic structure with low adherence and presence of supporting electrolyte between the polymer and the metal, or flat shiny, homogeneous and adherent polymer films. Variations in height or width of the potential steps and limits of the potential sweeps and sweep rate allowed the physical properties of the layer to be controlled progressively. (Author abstract). 30 Refs.

**082156 ELECTRICAL CONDUCTIVITY AND THERMOELECTRIC POWER OF POLYPYRROLE WITH DIFFERENT DOPING LEVELS.** The electrical conductivity and absolute thermoelectric power of the conducting polymer polypyrrole have been measured between approximately 4 K and 350 K. Normally doped films had a conductivity of  $26 \Omega^{-1} \text{cm}^{-1}$ , while lightly doped films had a conductivity of  $8 \Omega^{-1} \text{cm}^{-1}$ . The Mott variable range hopping model for electrical conductivity is obeyed at higher temperatures for both types. The thermoelectric power is approximately linear in temperature, reaching about  $5 \mu\text{V K}^{-1}$  at 200 K, but is sublinear at higher temperatures and becomes constant above about 300 K. The Kuivalainen model which explains the reported anomaly between optical and dc electrical conductivity gives a good fit to the experimental data. (Author abstract). 20 Refs.

**082157 PROCEEDINGS OF THE CONFERENCE ON ELECTRONIC PROCESSES IN CONDUCTING POLYMERS (A SATELLITE CONFERENCE ON THE 18TH INTERNATIONAL CONFERENCE ON THE PHYSICS OF SEMICONDUCTORS (ICPS-86)).** These volumes contain 54 papers. All these papers are abstracted and indexed individually. These papers report the new results in conducting polymer research and the future trends in conducting polymers. The topics covered are: polyaniline; electronic structure of conducting polymers; doped polyacetylenes; sulfur containing conducting polymers; halogen-bridged platinum complexes; and electrochemical results on the properties of conducting polymers. Technical and professional papers from this conference are indexed and abstracted with the conference code no. 10550 in the Ei Engineering Meetings (TM) database produced by Engineering Information, Inc.

**082158 FRONTIERS IN THE DEVELOPMENT OF POLYMERS AS ELECTRONIC MATERIALS.** Current applications of polymers as electronic materials are reviewed. Salient differences between the physics of electronic processes in polymers as opposed to those in network semiconductors are indicated, with emphasis on active research frontiers. Finally, promising technological and scientific opportunities are noted within the context of assessing the prospects for the growth of research and development efforts on conducting polymers. (Edited author abstract) 40 refs.

**082159 SOME POTENTIAL APPLICATIONS FOR CONDUCTIVE POLYMERS.** The list of potential applications for conductive polymers has grown slightly over the years since the inception of research activities. Two examples are described: all-solid-state polymer secondary batteries utilizing composites of electroactive and ion-conductive polymers, and photoelectrochromic devices based on combinations of semiconductors and electroactive polymers. Both of these applications utilize the electroactivity of the polymer, but in different manners. 16 refs.

**082160 POLYANILINE: PROCESSABILITY FROM AQUEOUS SOLUTIONS AND EFFECT OF WATER VAPOR ON CONDUCTIVITY.** The chemically-synthesized emeraldine base form of polyaniline is soluble in aqueous acetic acid solutions, in which it presumably exists as the 'doped' emeraldine acetate salt. Films having a conductivity of approx.  $0.5\text{--}2 \text{S/cm}$  may be cast from the solutions. These films may be converted to relatively flexible, free-standing, lustrous, copper-colored films of emeraldine base, which can in turn be converted to free-standing, lustrous, dark blue films of emeraldine hydrochloride ( $\sigma$  approx.  $1\text{--}2 \text{S/cm}$ ). The resistance of films of both emeraldine base and 50% protonated emeraldine hydrochloride decreases by a factor of approx. 2 when exposed to approx. 4 Torr of water vapor. The resistance increases only very slowly on removing the water vapor under dynamic vacuum, consistent with the postulated structure of emeraldine hydrochloride involving 'islands' of heavily-doped emeraldine base in a matrix of undoped or slightly-doped material. (Author abstract) 12 refs.

**082161 SOLUBLE CONDUCTING POLYMERS: THE POLY(3-ALKYLTHIENYLENES).** The conjugated poly(3-alkylthiénylenes) can be processed from solution and subsequently used as semiconducting and metallic polymers. Both as-synthesized and solution-cast films can be readily doped to give electrical conductivities that are quite high:  $\sigma$  approx.  $30\text{--}100 \text{S/cm}$ . Ultraviolet-visible absorption spectra of the neutral and doped forms have been obtained for solid films (as-synthesized and solution-cast) and for the polymers in solution. Excitation into the  $\pi\text{--}\pi^*$  transition (peak at  $\approx 2.8 \text{eV}$ ), leads to photoluminescence (peak at  $2.16 \text{eV}$ ). The Stokes' shift is consistent with radiative decay from photogenerated neutral bipolarons (exciton-polarons). From electron spin resonance measurements and spectroscopic data on the doped polymer in solution, we have determined the nature of the charge storage configurations. The results indicate that the spinless bipolaron is the lowest energy charge storage configuration on single poly(3-hexylthiénylene) macromolecules in solution. (Edited author abstract) 19 refs.

**082163 CONDUCTING POLYMERS: WHAT DOES THE FUTURE HOLD?** The conducting polymer field has continued its rapid expansion during the past 10 years since the discovery that an organic polymer, polyacetylene, could be doped to the metallic regime. A number of new conducting polymers have since been synthesized and many chemical, structural and physical studies have helped in elucidating the doping processes and electronic and magnetic properties of these materials; however, an adequate understanding of many fundamental phenomena will only be attained by further research. Such understanding will be assisted by the synthesis and study of new types of conducting polymers and composites. The first significant signs of technological applications of these polymers now appearing are expected to stimulate even more basic and applied research in this field in the future. (Author abstract) 83 refs.

**082164 EFFECTS OF MAGNETIC ORDER ON CHARGE TRANSPORT IN CONDUCTING POLYMERS.** We have studied the effect of charge carrier spin-magnetic ion interactions on charge transport in inhomogeneous polymers where the highly-conducting regions of the material order magnetically. This is the case of example in heavily  $\text{FeCl}_3$ -doped  $(\text{CH})_x$  or in polymer composites consisting of a magnetic metal or a magnetic semiconductor embedded in an insulating polymer. Our calculated results show that when the conduction is dominated by thin potential barriers as in the fluctuation-induced tunneling mechanism, the changes in magnetic order due to temperature or magnetic field cause large changes in resistivity. The possibility that the present mechanism can explain the measured positive magnetoresistance in  $\text{FeCl}_3$ -doped  $(\text{CH})_x$  is discussed. (Author abstract) 10 refs.

**082165 OVERDOPING AND THE CAPACITIVE EFFECT IN POLYPYRROLE.** Analyzing the nature of the changes stored in chemically synthesized polypyrrole by ac impedance and cyclic voltammetry, we have decomposed the total current into two components: a capacitive current and a non-capacitive one. The non-capacitive charge is found to be approximately constant, whereas the capacitive one can vary widely from one sample to another. We conclude that the interesting overdoping effect observed in polypyrrole can essentially be attributed to the capacitive charge. (Author abstract) 9 refs.

**082166 WATER EFFECTS IN POLYANILINE: A NEW CONDUCTION PROCESS.** We present NMR and conductivity measurements on polyaniline, which show that upon applying water vapor pressure: (i) protons exchange between the polymer and an adsorbed water phase; (ii) conduction is favored. The diffusion process of water in a pellet is investigated. Finally, we propose a

conduction mechanism based upon electron hopping between localized states, assisted by proton exchange. (Author abstract) 14 refs.

**082167 OPTICAL SPECTROSCOPY AND RESONANCE RAMAN SCATTERING OF POLYANILINE DURING ELECTROCHEMICAL OXIDATION AND REDUCTION.** In situ optical absorption and resonance Raman measurements are reported for the salt form of polyaniline. The Raman spectra show a strong dependence of the intensities on the electrochemical potential for blue laser excitation. Line shifts and new peaks were observed for green laser excitation. The behavior observed for the blue laser excitation is consistent with a decrease in preresonance molecular due to an upshift of the fundamental absorption during oxidation. The spectra for green and red laser excitations are characteristic of a change in benzoid-quinoid ring concentrations. Hysteresis behavior observed for the transmission of light at constant photon energy during cycling is interpreted as being due to diffusion processes of heavy counter-ions. (Author abstract) 9 refs.

**082169 ELECTRONIC STRUCTURE OF CONDUCTING POLYMERS FROM HETEROAROMATIC BICYCLIC COMPOUNDS.** A series of conjugated polymers based on indole and heteroaromatic bicyclic compounds (X, Y = NH, S, Se) is obtained as thin films on gold or conducting glass electrodes, using controlled-potential electrochemical methods. Synthesized in an oxidized state, most of them can be reduced electrochemically, accompanied by a color switching. X-ray photoelectron spectroscopy clearly shows the differences in electronic structure between the derivatives: two distinct redox states exist only when the conjugation pattern allows effective electron delocalization. (Author abstract) 16 refs.

**082170 ELECTRONIC STRUCTURE OF POLYTHIOPHENE.** We have used ultraviolet and X-ray photoelectron spectroscopy (UPS and XPS respectively) to study the electronic structure of the electrically conducting polymer polythiophene (PT) prepared electrochemically. The UPS and XPS valence band spectra of electrochemically reduced, insulating PT (i.e., PT<sup>0</sup>) are compared with corresponding spectra of thiophene in the gas phase and in the condensed phase, with the spectra of pure radiation polymerized PT<sup>0</sup>, and with the results of quantum chemical calculations based upon the Valence Effective Hamiltonian (VEH) and CNDO/S3 models. Excellent agreement is obtained between theory and

experiment. We have also noticed some unusual effects in XPS valence spectrum of PT<sup>0</sup>, and in the XPS core level spectra of doped PT (i.e., PT<sup>+</sup>) due to exposure of the samples to air. (Author abstract) 14 refs.

Wu, C.R. (Linköping Univ, Linköping, Swed); Nilsson, J.O.; Inganäs, O.; Salaneck, W.R.; Osterholm, J.-E.; Bredas, J.L. *Synth Met* v 21 n 2 Sep 1987, Proc of the Conf on Electron Processes in Conduct Polym, Part II, Vadstena, Swed, Aug 18-20 1986 p 197-202.

**082171 EFFECT OF AMMONIA ON THE PHYSICAL PROPERTIES OF POLYPYRROLE.** Electrical measurements and uv/vis/nir spectroscopy are used to investigate the influence of ammonia on electrochemically prepared polypyrrole. It is demonstrated that both a reversible and an irreversible change of the electronic properties of the polymer occur. Some possible origins of these changes are discussed, such as the formation of ammonia-anion complexes and a breaking of the polymer chains. (Author abstract) 11 refs.

**082172 SOME NEW ELECTROCHEMICAL RESULTS ON THE PROPERTIES OF CONDUCTING POLYMERS.** Electrochemical measurements were carried out with a PAR 176 potentiostat and a PAR 173 waveform generator. It is concluded that the electropolymerization is not only a linear chain growth with successive addition of monomers, but a complex reaction pattern with the competing addition of monomers, dimers and other oligomers at different reactive sites. 13 refs.

**082173 FOURIER TRANSFORM INFRARED STUDY OF LIGHTLY DOPED POLYTHIOPHENE UNDER D.C. ELECTRIC FIELDS.** We have studied the effect of a strong dc field on the IR absorbance bands of lightly FeCl<sub>4</sub><sup>-</sup>-doped polythiophene (PT) thin films. Application of a dc electric field <4 kV/cm caused large changes in the absorbances of the IR modes, especially in the C-H stretching, C-H in- and out-of-plane vibrational modes and in the bands corresponding to the thiophene ring stretching. Also the absorbances of the doping-induced bands changed substantially, but they relaxed close to the original values faster than the other modes after the field was switched off. Special care was taken to study the contribution of heating of the film to the observed results by measuring the temperature of the films both by using a thermocouple and by using the film itself as a sensitive temperature sensor. Various mechanisms including, e.g., structural changes in the disordered PT material, charge injection-induced polaron or bipolaron formation and doping continuation may contribute to the observed large changes in the IR modes of PT. (Edited author abstract) 8 refs.

**082178 ELECTROCHEMICALLY CONTROLLED RELEASE OF DRUGS AND OTHER CHEMICALS.** Exploration of new methods for the timed release of drugs in which the release rate could be varied at will has led to the invention of an electrochemical device. A polymer film is coated on an electrode, the film is loaded with drug by covalent or ionic bonds, and as needed the drug is released by passing a small current through the film. The current level controls the release rate. An approach of current interest involves the use of conducting polymers which in one redox state have charged backbones and bind counter-ions. If the counter-ion is a drug ion it can be bound and released by neutralizing the charge on the polymer backbone. This has been demonstrated using polypyrroles and certain polythiophenes which will bind either anions such as acetylsalicylate or cations such as dopamine. (Author abstract)

**082180 EFFECT OF SOLVATION IN CONDUCTING POLYMERS.** The incorporation of solvent molecules into solid-state organic conductors affects both electrical and mechanical properties of the conducting complexes. Evidence for this has been appearing from the numerous laboratories currently involved in conducting polymer research. On compiling these examples, common rationale for the observed effects can be formulated based largely on the behavior of smaller molecules as found in the organic literature. Nonetheless, the examples must be considered on a case-to-case basis. In assigning the source of solvent effects, the determination of whether solvation is occurring on the charged polymer backbone or on the (oppositely charged) dopant counterion is critical. Among the proposed causes of solvent effects are solvent-separated ion pairing, charge depinning, and plasticization. (Author abstract) 15 refs.

**082181 DYNAMIC CRACK GROWTH IN A VISCOELASTIC MATERIAL.** Dynamic crack growth in a viscoelastic material is investigated. The present work concentrates on a Maxwell liquid. A new feature of the present analysis is the consideration of the effects of a finite cohesive zone, in which a constant cohesive stress  $\sigma_0$  acts, whose extent may be comparable with the length scale of the applied loads. A critical crack opening displacement fracture criterion is used. When  $\sigma_0$  is sufficiently large, this is demonstrated to reduce to the energy release rate criterion, while finite  $\sigma_0$  provides a rudimentary model of a craze zone such as exists adjacent to a crack tip in a viscoelastic polymer. The solution to be presented thus serves the dual purpose of providing an explicit realization of the near-tip situation, and of assessing the influence of a craze zone during dynamic fracture of a polymer. 10 Refs.

**082182 SPIRAL CRACK PROPAGATION CONFINED TO A SURFACE ZONE OF A CROSS-LINKED POLYMER.** The purpose of this letter is to report an unusual mode of crack propagation observed in the course of dynamic mechanical analysis of crosslinked samples prepared by radiation polymerization of liquid triethylene glycol dimethacrylate which was confined between glass sheets. Samples were subjected to a small sinusoidal strain which alternated between frequencies of 1.1, 11, and 110 Hz during heating from  $-100^\circ\text{C}$  at  $2.5^\circ\text{C min}^{-1}$ . Unusual fracture modes were observed in the case of samples prepared with doses in the range 0.4 to 2.0 Mrad. In the region above the glass transition temperature ( $T_g=120^\circ\text{C}$ ) some samples suddenly disintegrated into fragments. It would appear that

heating results in samples in which a crack propagates more readily in a surface zone than in the interior. 7 Refs.

**082183 POLYMER DEGRADATION BY CRAZING AND ITS STUDY BY SMALL ANGLE SCATTERING TECHNIQUES.** Craze formation and breakdown in polymers is reviewed. Small angle scattering, particularly when combined with information obtainable from transmission electron microscopy, has proved to be a powerful technique for the study of crazes. The existence of X-rays, neutrons and electrons has helped both in the interpretation of the basic form of craze scattering patterns and in permitting the study of a range of problems. The intensity of X-rays from synchrotron sources has permitted the study of such failure processes as mechanical fatigue and impact in real-time. Neutron radiation has proved useful in the study of environmentally-induced crazes while electron radiation is used for the examination of crazes in thin films. The majority of the work on crazing has been done in single phase amorphous polymers, particularly polystyrene and polycarbonate, but the rubber toughened styrenics in which crazing is an important toughening mechanism offer a fruitful field of study. It is in these latter systems that impact processes can be studied by small angle scattering. (Edited author abstract) 134 refs.

**082184 CRAZES AND FRACTURE IN POLYMERS.** A review of crazes in glassy thermoplastic polymers is presented with particular emphasis on those aspects of craze properties that influence and control fracture behavior. Both crazes as they normally occur, and crazes at the top of cracks are covered. The occurrence of crazes, their microstructure, the stress distribution within them and the nature of craze fibrils are discussed. Theoretical treatments of the effect of crazes on polymer fracture are reviewed. (Author abstract) 113 refs.

**082185 ANALYZING POLYMER CRAZING AS QUASIFRACTURE.** This paper deals with a viscoelastic boundary element method for analyzing a polymer quasifracture usually called a craze in polymers. A time-dependent boundary stiffness is considered on the quasifracture envelope surface. The viscoelastic property of the glassy polymer is represented by a generalized Kelvin model with multiple retardation times. According to the linear viscoelastic correspondence principle, the associated elasticity solution can be solved by applying the general integral boundary element method. Then the viscoelastic solution in the time domain can be obtained by applying a collocation Laplace inversion transformation. Using these methods, the quasifracture problem composed of an isolated craze opening with time-dependent stiffness traction in a stressed rectangular plate is analyzed. The displacement profile and the stress distribution around the craze envelope surface are computed. (Author abstract) 19 refs.

**082186 MATHEMATICAL MODEL OF CREEP OF PHENYLONE IN WATER.** A study has been made of the creep of phenylone in water and a mathematical model of the process is proposed. It is shown that in the temperature interval  $20-60^\circ\text{C}$   $\text{H}_2\text{O}$  adsorption plays a

limiting role in this process. It was found that the coefficient of  $\text{H}_2\text{O}$  diffusion is a function of the load. (Author abstract) 4 refs.

**082187 INFLUENCE OF PHYSICAL AGING AT CONSTANT TEMPERATURE ON THE SHEAR CREEP OF AMORPHOUS POLYMERS.** The theory of linear viscoelastic behaviour under the influence of aging at constant temperature is briefly reviewed. Emphasis is placed on the evaluation of the retardation time - age shift relation from creep experiments under proceeding aging. The shear behaviour of a technical polystyrene was carefully measured at four temperatures just below the glass transition temperature, systematically varying the time elapsed between the temperature quench and the start of the creep experiment. The result could be accurately described by Struik's theory of viscoelastic behaviour under aging. The dependence of the retardation times on age and temperature in the vicinity of the glass transition is discussed. (Author abstract) 13 refs.

**082190 SYNTHESIS AND ESTEROLYTIC REACTIONS OF LINEAR AND CROSS-LINKED ASYMMETRIC IMIDAZOLE-CONTAINING POLYMERS.** Asymmetric linear and cross-linked imidazole-containing polymers were prepared from 1-[2(S)-methylbutyl]-4-vinylimidazole and 1-[2(S)-methylbutyl]-5-vinylimidazole. The esterolytic reactions of these linear and cross-linked asymmetric polymers with the enantiomeric substrates (R)- and (S)-4-(3-methylpentadecanoyl)-3-nitrobenzoic acid (R)- and (S)- $3\text{-Me}_{15}$  were studied by measuring the pseudo-first order kinetics of the solvolysis of these enantiomeric substrates in the presence of these

asymmetric polymers. The linear homopolymers and copolymers of 1-[2(S)-methylbutyl]-4- and 5-vinylimidazole showed hydrophobic and electrostatic effects in the solvolysis of the enantiomeric substrates with these linear asymmetric polymers. Cross-links were introduced into these asymmetric polymers to increase the rigidity and reduce the number of conformations available to the polymer. Neither the linear nor the cross-linked asymmetric polyvinylimidazoles showed enantioselectivity in the solvolysis of these enantiomeric substrates. The hydrophobic interactions and the reduced conformational mobility through crosslinking were not strong enough to bring about enantioselectivity in the solvolysis of these enantiomeric substrates. **082191 RUBBER ELASTICITY: A SCALING APPROACH.** A scaling analysis of the rubber-like elastic behavior of a crosslinked polymer network is presented which incorporates the two most salient contributions to the free energy of deformation: the chain connectivity of the segments and the restrictions on the chain configurations due to entanglements. The affine deformation of the junction points is assumed. A tube model is used to discuss the deformation dependence of the entanglement constraint parameter. (Edited author abstract) 18 refs.

**082192 MOLECULAR WEIGHT RELATIONS FOR CROSSLINKING OF CHAINS WITH LENGTH AND SITE DISTRIBUTION.** Many polymer networks are formed by crosslinked polymer chains through reactive sites distributed along the chains. How these sites are distributed as well as the chain length distribution can have a significant effect on properties like the gel conversion and molecular weight. Previous treatments have used simplifying approximations. This paper eliminates these approximations and derives computational formulae for weight average molecular weight and gel point for polymer chains of any length and reactive site distribution. Three types of crosslinking are considered: direct coupling of chains (homopolymerization), direct coupling through propagation, and coupling through copolymerization with small monomers. (Edited author abstract) 29 refs.

**082193 THEORETICAL CONSIDERATIONS OF SCISSION AND ENDLINKING REACTIONS IN IRRADIATED POLYMERS.** The pros and cons of the experimental and theoretical techniques used for following the crosslinking and scission reactions in irradiated polymers are briefly discussed. Special emphasis is given to the role of the reactions of main chain scission and endlinking and its influence on the analysis based on gelation theories. It is shown that increased initial scission could have a significant effect as well as the restricted or unlimited endlinking reaction which is not distinguished from the conventional reaction of crosslinking. Modified theoretical concepts could bring more insight into the nature of radiation induced reactions in polymers. (Author abstract) 21 refs.

**082196 PHOTOCHEMICAL CROSSLINKING OF POLY(PHENYLQUINOXALINES) IN THE PRESENCE OF AROMATIC AZIDES.** Crosslinking of several poly(phenylquinoxalines), induced photochemically in the presence of 2,6-di(4'-azidobenzal)cyclohexanone, has been studied by EPR spectroscopy, using a paramagnetic probe, and by sensitometry. In some poly(phenylquinoxalines) photochemical crosslinking resulting in a loss of solubility has been found to proceed exclusively within a relatively narrow interval of oxygen partial pressure, delimited by lower and upper critical values. This mode of crosslinking is possible because of the chemical structure of the repeat unit. (Author abstract) 11 refs.

**082198 EFFECT OF CROSSLINK DENSITY ON THE MOLECULAR RELAXATIONS IN DIEPOXIDE-DIAMINE NETWORK POLYMERS. PART 1. THE GLASSY REGION.** The effects of systematically varying the crosslink density on the mechanical relaxations in the glassy region of typical highly crosslinked diepoxide-diamine polymers are reported. Activation enthalpies and intensities for the  $\beta$  relaxation have been measured using a torsion pendulum at 1 Hz. The glyceryl groups, which are thought to be responsible for this process, are divided into a number of categories defined by the structure of the surrounding matrix. Concentrations of these units are calculated using probability theory, and a correlation is obtained with three measures of the relaxation intensity. In the case of nonstoichiometric networks, variations in the intensity of the  $\beta$  relaxation are interpreted in terms of the simultaneous motion of each class of glyceryl group. The manner in which these processes combine to produce a composite peak appears to be unimportant. For the  $\gamma$  relaxation ( $-140^\circ\text{C}$ ), it is shown that at least four methylene units are needed in the diamine component before the process is observable, whereas only two consecutive methylene units in the center of the diepoxide molecule produce the relaxation. (Author abstract) 33 refs.

Charlesworth, John M. (Melbourne Univ, Parkville, Aust). *Polym Eng Sci* v 28 n 4 Feb 1988 p 221-229.

**082199 EFFECT OF CROSSLINK DENSITY ON MOLECULAR RELAXATIONS IN DIEPOXIDE-DIAMINE NETWORK POLYMERS. PART 2. THE RUBBERY PLATEAU REGION.** A comparison of the

predictions of the theory of rubber elasticity with the experimentally observed variation of the shear storage modulus, G, as a function of crosslink concentration shows that deviations occur when the network strand concentration in diepoxide-diamine polymers exceeds approximately 1.5 mole kg<sup>-1</sup>. The rapid rise in G above this level is accounted for in terms of the increasing importance of non-Gaussian chain statistics and steric interactions. It is also established that the contribution from entanglements is significant and the behavior over the entire crosslink density range can be described by an equation. (Edited author abstract) 46 refs.

Charlesworth, John M. (Melbourne Univ, Parkville, Aust). *Polym Eng Sci* v 28 n 4 Feb 1988 p 230-236.

**082200 RANDOM HYPERGRAPHS AND TOPOLOGICAL GELATION CRITERION FOR CROSSLINKED POLYMER SYSTEMS.** A class of hypergraphs named polygraphs, especially suitable for modeling polymer systems, is defined and we discuss in detail the conditions which give rise to the Giant Component in the polygraph. This problem is analogous to gel formation in a crosslinked polymer system. To this end an equivalence class of polygraphs with given connectivity is defined and characterized by a specially introduced probabilistic representation. Our Topological Gelation Criterion is applicable to systems that may be far from thermodynamic equilibrium and need not necessarily be random. The criterion applies to polymers, superpolymers, cell aggregates, immunocyto-chemical systems and other systems. (Author abstract) 26 refs.

**082201 DETERMINATION OF CROSS-LINK DENSITY IN THERMOSET POLYMERS BY USE OF SOLID-STATE <sup>1</sup>H NMR TECHNIQUES.** Solid-state <sup>1</sup>H NMR techniques were used to determine the cross-link density of highly cross-linked polymers common in the aerospace industry. As the temperature was increased, the spin-spin relaxation times of cross-linked epoxy polymers were observed to reach a plateau value which increased linearly with increasing molecular weight between cross-links, as predicted by theory. The results show that, for the epoxy system studied, approximately 10 rotatable backbone bonds are needed to form a statistical segment, the portion of the polymer backbone that moves independently of the other backbone motions. (Author abstract) 13 refs.

**082202 PREPARATION METHODS AND STRUCTURE OF HYDROGELS.** Hydrogels are water-swollen networks (cross-linked structures) of hydrophilic homopolymers or copolymers. They are three-dimensional and the cross-links can be formed by covalent or ionic bonds. Often, weaker forces such as van der Waals forces and hydrogen bonds can serve as cross-links, thus forming swollen networks which behave as hydrogels. Finally, semicrystalline, uncross-linked hydrophilic polymers may form hydrogels upon swelling since the crystallites act as physical cross-links and do not dissolve in water. Hydrogels may be classified in various ways depending on their chemical or physical structure. A common classification, especially useful in biomedical applications, includes neutral hydrogels, ionic hydrogels, and swollen interpenetrating polymeric networks (IPN). 53 refs.

**082203 HYDROGEL SURFACES.** The surface region of hydrated hydrogel polymers represents a unique environment different from the surfaces of almost all other

materials. This surface region is characterized by high chain mobility, gradients of composition, heterogeneous chain lengths, amphiphilic character, and unique water structuring. These are all properties that also contribute to the difficulty in precisely analyzing and characterizing hydrogel surfaces. This chapter will attempt to sum up some of the generally accepted ideas about hydrogel surfaces and will consider aspects of hydrogel surfaces that are presently the subject of some controversy. 51 refs.

**082206 REACTIVE POLYMERS: DESIGN CONSIDERATIONS, NOVEL PREPARATION AND SELECTED APPLICATIONS IN ORGANIC CHEMISTRY.** Crosslinked reactive polymers with novel structures have been prepared from the corresponding monomers or by newly developed chemical modification reactions. These include the preparation of polymers with two or three carbon spacer groups between backbone and functionality, the first preparation of a Grignard reagent on an insoluble polymer, and some new copper mediated chemical modification reactions resulting in C-C bond formation. Novel applications of these polymers in asymmetric synthesis regenerable polymeric protecting groups, super-nucleophilic catalysts, polymeric separation media for HPLC, as well as aids in the determination of reaction mechanisms, have been investigated. Microenvironment effects within the polymer beads are shown to be important when considering the use of an insoluble reactive polymer. (Author abstract) 103 refs.

**082208 MOLECULAR ORIENTATION IN LIQUID FIBERS OF NEMATIC POLYMERS.** The degree of macroscopic orientation of molten fibrous samples of nematic semiflexible polymers has been investigated by X-ray diffraction. Melting of highly oriented fibers is followed by a partial loss of macroscopic orientation but does not produce collapse of the fiber. The residual orientational order remains unaltered for a considerable time. The degree of orientational order depends on the temperature and undergoes odd-even fluctuations according to the parity of the number of carbon atoms contained in the flexible part of the monomer unit. Extrapolation of the order parameter to the isotropization temperature leads to a value of about 0.63 for even-type polymers and to about 0.47 for odd-type polymers. An intermediate value is found for a copolymer containing equal amounts of even and odd monomer units along the polymer chain. (Author abstract) 13 refs.

**082209 INVERSION OF THE TEMPERATURE DEPENDENCE OF CRYSTALLIZATION RATES DUE TO ONSET OF CHAIN FOLDING.** Crystallization rate experiments performed on the uniform alkanes C<sub>24</sub>H<sub>49</sub> and C<sub>19</sub>H<sub>39</sub>, by both differential scanning calorimetry and in situ X-ray diffraction (using a synchrotron source), have revealed that these rates, including both primary nucleation and growth, pass through a minimum with increasing supercooling. The first (expected) increase and subsequent (unsuspected) decrease correspond to extended-chain (E) crystallization, the renewed increase beyond the minimum corresponding to chain-folded crystallization with the fold period *l* being smaller than *L* but larger than *L*/2, where *L* is the extended chain length. The observed effects, which have come to light owing to the availability of ultra-long and uniform n-alkanes, help to provide new insight into the primary stages of chain-folded crystallization, with many potential consequences, some of which are discussed. (Edited author abstract) 15 refs.

**082210 SOLVENT-INDUCED CRYSTALLIZATION OF A COMPATIBLE POLYMER BLEND.** We studied solvent-induced crystallization (SINC) in a compatible blend of poly(butylene terephthalate) (PBT) and a polyarylate (PAr) over a range of blend compositions and temperatures; liquid acetone was the crystallizing agent. Acetone transport kinetics were followed by mass uptake measurements in thin films and by optical microscopy. Crystallization kinetics were followed by density measurements. For the 0.2 mm thick films used, those with higher weight fractions of PBT (50 to 60 percent by weight) exhibit diffusion controlled transport and crystallization

over the entire range of temperatures studied (0 to 55°C). Those with lower weight fractions of PBT (approx. 30 percent by weight) display Case II sorption and crystal growth controlled crystallization at 0°C. (Edited author abstract) 24 refs.

**082211 SOME FEATURES OF THE CRYSTALLIZATION OF POLYVINYLIDENEFLUORIDE.** Differential scanning calorimetry has been used to investigate differences in the structure of PVDF specimens synthesized at various temperatures. The thermograms obtained for melting and crystallization give evidence that there are differences between the specimens investigated with respect to the degree of order in the crystalline structure. It is suggested that the differences established are caused not so much by a change in the regularity of the polymer chain's structure of the 'head-to-tail' type but rather by branching of the polymers which can increase substantially as the temperature of synthesis of the initial polymer is raised. (Author abstract) 5 refs.

Madorskaya, L.Ya. (Plastopolimer, Okhtinsk, USSR); Loginova, N.N.; Kastorskii, L.P.; Kuz'michev, O.V.; Maksimov, V.L.; Lobanov, A.M. *Polym Sci USSR* v 28 n 6 1986 p 1433-1440.

**082212 CRYSTALLIZATION, THERMAL BEHAVIOR, AND COMPATIBILITY IN ISOTACTIC POLYSTYRENE/POLY(O-CHLOROSTYRENE-CO-P-CHLOROSTYRENE) BLENDS.** The dependence of the kinetics of crystallization and melting behavior in isotactic polystyrene/ poly-o-chlorostyrene-co-p-chlorostyrene (iPS/P(o-CIS-co-p-CIS) blends on temperature, thermal history, and blend composition has been investigated. The crystallization rate at a given temperature and copolymer composition decreases with increasing copolymer content in the blend when the samples are premelted. These effects can be ascribed to the reduction of mobility of the crystallizable chains due to the presence of the copolymer and to the decrease in the number of heterogeneous iPS nuclei as a result of the premelting process. The Avrami exponent values and the analysis of the blend morphology indicate that the growth mechanism of the crystals is strongly influenced by thermal treatment. From the comparison of the phase diagram for the isotactic polystyrene-containing blend with that of the atactic-containing blend, it can be concluded that in the amorphous state polystyrene with a regular configuration is slightly less compatible with the P(o-CIS-co-p-CIS) than is polystyrene with random configuration. **082213 CRYSTALLIZATION KINETICS OF POLY(P-PHENYLENE SULPHIDE): EFFECT OF MOLECULAR WEIGHT.** The crystallization behavior of poly(p-phenylene sulfide) (PPS) has been studied in terms of linear crystal growth rates and overall rates of bulk crystallization as functions of molecular weight and temperature. In addition, nucleation densities were estimated for PPS crystallized from the melt. The overall rate of bulk crystallization was described by the Avrami equation. In the range of molecular weights studied (24000-63000), crystal growth rates and overall rates of bulk crystallization decreased as the molecular weight increased. However, the effect was not particularly large. The estimated nucleation densities indicated a decrease by a factor of 32 as the molecular weight decreased. The linear crystal growth rate data were analyzed in terms of several proposed models. The data seemed to conform

very well to an 'inverse' logarithmic function of the number-average molecular weight recently proposed by Cheng and Wunderlich. (Author abstract) 30 refs.

**082214 THEORETICAL ASPECT OF CRYSTALLIZATION TEMPERATURE AT MAXIMUM CRYSTAL GROWTH RATE.** The ratio of the temperature at which the nucleation rate or the crystal growth rate is maximum to the melting temperature was predicted theoretically as a function of two parameters: one is the ratio of the activation energy of migration through the nucleus-melt interface to the heat of fusion and the other is the ratio of the mean surface energy of a mole of repeat unit to the heat of fusion. The ratios of  $T_{c, max}/T_m$  were evaluated from the above two parameters. (Edited author abstract) 61 refs.

**082216 KINETICS OF POLYMER CRYSTALLIZATION. I. DISCRETE AND CONTINUUM MODELS.** The kinetics of growth of lamellar crystals by chain folding of polymer molecules are described by Markov rate processes whose states are representations of the edge of a lamella. The dynamic reversibility of these processes allows their equilibrium distributions to be found and these describe states of steady crystal growth. (Edited author abstract) 23 refs.

Gates, D.J. (CSIRO, Canberra, Aust); Westcott, M. *Proc R Soc London Ser A* v 416 n 1851 Apr 8 1988 p 443-461.

**082217 KINETICS OF POLYMER CRYSTALLIZATION. II. GROWTH REGIMES.** Exact expressions are found for the steady-state growth rate of a portion of the edge of a lamellar crystal in terms of the number of polymer segments in the portion, the nucleation rate on the edge and the folding rate of polymer chains. Both hexagonal and square crystal structures are analysed. Simpler expressions are given in various limiting cases. (Edited author abstract)

**082218 THERMAL AND CRYSTALLIZATION BEHAVIOR OF ENGINEERING POLYBLEND. I. GLASS REINFORCED POLYPHENYLENE SULFIDE WITH POLYETHYLENE TEREPHTHALATE.** The thermal and crystallization behavior of blends of glass fiber reinforced polyphenylene sulfide (PPS) with polyethylene terephthalate (PET) has been reported. The blends showed two overlapping melting peaks and two separate crystallization peaks. The heat of crystallization of PPS was found to decrease continuously with increasing PET content, whereas the heat of crystallization of PET was found to increase with increasing PPS content. This indicates that the degree of crystallinity of PPS is reduced whereas that of PET is increased as a result of blending. (Edited author abstract) 9 refs.

**082219 ON CRYSTALLIZATION OF COMBLIKE POLYMETHACRYLATES.** The authors examined the

crystallization of poly(octadecyl methacrylate) and a copolymer of octadecyl methacrylate and hexadecyl methacrylate. While we were able to identify two distinct melting endotherms in these materials as described by I. Sobotnik and I.V. Sochava, we believe that they exist in just a single crystalline modification and the two melting points are the result of different crystallization processes. The data show no evidence for polymorphism and thus are incompatible with this interpretation. A different interpretation has to be sought, therefore, for the double melting peaks. It is reasonable to postulate that quenching leads to extremely rapid nucleation and crystallization, resulting in many small crystals of poor quality with a low melting point. The broader X-ray diffraction peaks and more pronounced amorphous halo of the quenched sample in comparison with that of the high melting polymer support this view. 8 refs.

**082220 PACKING OF LONG-CHAIN CYCLOALKANES IN VARIOUS CRYSTALLINE MODIFICATIONS: AN ELECTRON DIFFRACTION INVESTIGATION.** The structure and thermal behavior of long-chain cycloalkanes  $(CH_2)_n$  with  $n = 48, 72, 96, 144$  and 288 have been investigated by electron diffraction, WAXS and SAXS analysis. Five different modifications have been characterized by their subcells as a function of ring size, crystallization conditions and temperature. The rings adopt, in all modifications, a conformation with two straight stems connected by folds. Similarity with the polyethylene lattice is achieved only for  $n \geq 144$ . In this case, the stems are perpendicular to the layer surface and pack in the well-known orthorhombic subcell regardless of whether the rings are crystallized from solution or melt.  $(CH_2)_{96}$  forms the same type of subcell when crystallized from the melt, but the stems are oblique to the layer surface. Rings of all sizes undergo a transition into a phase in which the stems are arranged similarly as in the 'rotator phase' of linear paraffins.  $(CH_2)_{72}$  and  $(CH_2)_{96}$  exhibit additional transitions at lower temperatures. One significant feature of some transitions is the change of conformation and length of the folds. (Author abstract) 21 refs.

**082221 SOLID STATE REACTIONS AND TRANSITIONS IN HIGH POLYMERIC SYSTEMS III. THE BULK CRYSTALLIZATION OF LANTHANIDE-CATALYTICALLY POLYMERIZED POLYDIENES.** For the mechanism of isothermal bulk crystallization of high polymers, beside the nucleation and growth steps, the unimpingement of growing crystal aggregates should be taken into account for the modification of the Avrami equation. The derived equation is satisfactorily verified by the isothermal bulk crystallization of lanthanide-catalytically polymerized polybutadiene (Ln-PB), polyisoprene (Ln-PIR) and their copolymers (Ln-PB/IR). Furthermore, the proposed mechanism is identified by the change of morphological state during the course of crystallization of the corresponding cast film of Ln-PB/IR (92/8) at  $-60^\circ\text{C}$ . Upon examination of the influence of entanglement on crystallization rate is found that two entanglement stages exist. (Edited author abstract). 27 Refs.

**082222 APPLICATION OF THE PARALLEL AVRAMI MODEL TO CRYSTALLIZATION OF POLY(ETHERETHERKETONE).** A reexamination has been made of the parallel Avrami model recently proposed by C. Velisaris and J. Seferis to describe the non-isothermal crystallization of poly(etheretherketone), PEEK. Results show that, based on considerations of morphology development, the crystallization process with the larger Avrami exponent has the higher melting point, whereas the process with the smaller Avrami exponent has the lower melting point. In addition, the author used the

infinite crystal melting point, as required by crystallization theory, to determine the Avrami rate parameters for the two processes. (Edited author abstract). 28 Refs.

**082224 HYDROSILYLATION CURE OF POLYISOBUTENE.** A liquid polyisobutene oligomer with unsaturated chain ends undergoes hydrosilylation with  $\text{HMe}_2\text{SiOMe}_2\text{SiOMe}_2\text{SiH}$  or  $\text{Si}(\text{OMe}_2\text{SiH})_4$  to give higher molecular weight polymers or elastomers. A major side reaction consumes SiH to give redistributed siloxane in the resulting polymers and gaseous silanes and siloxanes as by-products. A second side reaction results in loss of reactivity in the oligomer due to a shift of the terminal double bond to an internal position. If the side reactions are taken into account, it is possible to forecast quantitatively molecular weight, gel point and modulus from the conversions of SiH,  $\text{C}=\text{CH}_2$  and the chain entanglement concentration reported for polyisobutene in the literature. **082227 MICROWAVE AND RADIO-FREQUENCY CURING OF POLYMERS.** The objectives of this study were to (i) identify suitable polymers and their conventional curing systems; (ii) estimate market potential for microwave/radio frequency curing of these selected materials; (iii) compare conventional and microwave/radio frequency technologies. In this report, the polymers produced and consumed in Canada and their conventional curing methods are reviewed, potential curable polymers are identified and their volumes are determined; then, energy requirements for polymer curing using various conventional curing methods are calculated; costs for raw material and process related preparation and relevant energy consumptions are determined. Based on the results of these studies, finished product costs by conventional curing methods are calculated using a cost & economics model. The microwave/radio frequency curing of polymers are reviewed, the characteristics of curable polymers are discussed and the energy requirements for microwave/radio frequency curing are calculated. Finally, using these findings, a market penetration study is carried out to determine the potential Canadian market for microwave/radio frequency curing of polymers. (Author abstract) 54 refs.

**082228 NEW METHODS FOR PREPARING ORGANIC LAYERED PHOTOCONDUCTORS.** As E.P.A. emission requirements become more stringent with regard to effluents entering the atmosphere, and as the cost of solvents escalates, high energy radiation curing becomes a much more attractive alternative for the fabrication of layered organic photoconductors (OLP) compared to high volume thermal curing. The OLP may be composed of several layers coated sequentially on a substrate: a binder layer, a charge generation layer (CGL) and charge transport layer (CTL). The binder layer improves adhesion of the CGL to the substrate. We have employed electron beam curing to formulate the binder layer and CGL. For the latter, charge generation compounds such as chlorodiane blue (CDB) or squaraine dyes were dispersed in radiation conversion acrylates and electron beam cured at 5-10 Mrad. A CTL was overcoated, and the electrical properties of the resulting photoconductors measured on a tester used to simulate the photocopying process. The photoconductors derived from radiation cured CGLs held charge during dark decay and discharged upon illumination. These data were compared with a commercial OLP and found to behave similarly. (Author abstract) 31 refs.

**082229 PERMEABILITIES OF RADIATION CURED MATERIALS.** The permeability of radiation cured materials to oxygen and water molecules was investigated. Several classes of radiation curable materials were studied, including: epoxy, urethane, polyether, polyester, and aliphatic acrylates. Permeabilities were measured as a function of irradiation dose for Ultra-Violet and Electron Beam sources. The effect of cross-link density on permeability was examined by varying the functionality of the molecule and the degree of cure. The results were interpreted in terms of structure/property relationships. (Author abstract) 7 refs.

## Decomposition

**082230 SOME CHARACTERISTIC DEPENDENCES IN THE ANALYSIS OF THE THERMAL DECOMPOSITION AND GLASS TRANSITION OF AMORPHOUS POLYMERS.** An attempt was made in this study to find some correlations between the kinetic parameters of thermal decomposition based on the free volume theory, which are analogous in form to the correlations for the glass transition process. Based on experimental evidence, the following conclusions can be drawn: the series of characteristic dependences, tested for the glass transition process, is also valid for the thermal decomposition of polymers analyzed by thermal analysis if the corresponding values of  $T_d$  and  $U_d$  are substituted for  $T_g$  and  $U_g$ . In the thermal analysis of the thermal decomposition of a polymer, we can determine the kinetic parameters, for example  $U_d$ , which are organically correlated with the glass transition of the polymer and are a function of ratio  $f_d/f_g$  as for the glass transition. 21 refs.

**082231 SPINODAL DECOMPOSITION OF THE POLYMER BLEND DEUTERIUM POLYSTYRENE (d-PS) AND POLYVINYL METHYLETHYLETH (PVME) STUDIED WITH HIGH RESOLUTION NEUTRON SMALL ANGLE SCATTERING.** Decomposition of a polymer blend in the miscibility gap has been studied by small angle scattering of neutrons, using a double crystal diffractometer. It covers a range which connects the region of elastic light scattering and, at the upper end, the region of conventional neutron small angle scattering instruments. The decomposed structure in the miscibility gap can be described by a characteristic length  $R$  which increases with time between 7 and 25 min. At longer times, the growth follows a more linear power law. This behavior is consistent with predictions of the domain growth for liquid mixtures and is estimated by using the self diffusion constant, viscosity, and the surface energy of the polymer. (Edited author abstract) 15 refs.

**082232 PRIMARY THERMAL FRAGMENTATION PROCESSES IN POLY(ETHYLENE OXALATE) INVESTIGATED BY MASS SPECTROMETRY.** The primary thermal decomposition mechanism of poly(ethylene oxalate) (PEO) has been investigated by pyrolysis-mass spectrometry. Several mass spectrometric techniques have been used in order to identify compounds present in the pyrolysis mixture: comparison of electron impact and chemical ionization spectra, high resolution accurate mass measurements and tandem mass spectrometry (daughter and parent ion spectra). The results obtained indicate that intramolecular exchange reactions predominate in the primary thermal fragmentation processes yielding cyclic oligomers up to tetramer. No other pyrolysis products were detectable under our experimental conditions. PEO, prepared by condensation polymerization, was shown by  $^1\text{H-NMR}$  to contain up to 7% of diethyleneglycol (DEG) units along the polymer chain. A small amount of cyclic oligomers containing DEG units was detected among the pyrolysis products from PEO. (Edited author abstract). 15 Refs.

Ballistreri, Alberto (Univ di Catania, Italy); Garozzo, Domenico; Impallomeni, Giuseppe; Montaudo, Giorgio. *Polym Degradation Stab* v 21 n 4 1988 p 311-321.

**082233 GAS CHROMATOGRAPHIC AND CAPILLARY GAS CHROMATOGRAPHIC-MASS SPECTROMETRIC ANALYSIS OF THERMAL DECOMPOSITION PRODUCTS OF LIQUID CRYSTAL POLYMERS.** The thermal decomposition products of a series of liquid crystalline poly(azomethine ester)s and their model compounds of low molecular mass were investigated. The volatile gaseous products evolved in Curie-point pyrolysis at 500°C were analyzed using a Porapak S column and a thermal conductivity detector of high sensitivity. The less volatile aliphatic and aromatic products evolved in flash pyrolysis of 500°C were analyzed

by gas chromatography-mass spectrometry. The decomposition of the ester group resulted in carbon monoxide and carbon dioxide. The polymers containing methoxy substituent groups gave higher amounts of carbon monoxide and methane, indicating cleavage of the methoxy group. The phenyl undecanoate moiety of the polymers resulted in phenol and p-cresol. (Edited author abstract) 10 refs.

Blazso, M. (Hungarian Acad of Sciences, Budapest, Hung); Zelei, B.; Gandhe, B.R.; Sek, D. *J Anal Appl Pyrolysis* v 11 Oct 1987, Proc of the 7th Int Symp on Anal and Appl Pyrolysis, Reading, Engl, Sep 15-19 1986 p 233-244.

**082234 THERMAL DECOMPOSITION OF SEGMENTS WITH TWO AROMATIC RINGS IN THERMOSTABLE MACROMOLECULES.** Pyrolysis-gas chromatographic-mass spectrometric studies on a series of pseudo-ladder polymers were performed. The pyrolysis at 650°C affects only the aryl ether segments of aryl ether derivatives of the poly[bis(benzimidazobenzisquinoxinones)]. The formation of the volatile thermolysis products are interpreted by the chemistry of the segments decomposed. The pyrolysis of 4,4'-dioxiphenylene segments results in 4-phenylphenol, analogously to the thermolysis of 1,4-dioxiphenylene which produces phenol. In contrast, 2,7-dihydroxynaphthalene segments decompose producing 2,7-dihydroxynaphthalene and 2-naphthol, analogously to the decomposition of 1,3-dioxiphenylene which releases resorcinol and phenol. (Edited author abstract) 6 refs.

**Defects** See Also POLYETHYLENES—Crystalline; POLYETHYLENES—Dielectric Properties.

**082235 STRUCTURE AND DEFECTS OF A LINEAR CHAIN POLYMER FILM; GeO PHTHALOCYANINE EPITAXIALLY GROWN ON KCl.** Epitaxial film of GeO phthalocyanine polymer grown on KCl has been investigated by direct observation of molecular images and electron diffraction. The film is composed of many crystallites oriented in two directions. The mechanism of the epitaxial growth of an organic crystal has been related to the determination of a staggering angle of the molecules stacked in polymer chains. Prominent diffuse scatterings have been observed and their origin has been revealed to be the existence of stacking faults in the crystal. The molecular orientation at the fault is discussed. (Author abstract) 12 refs.

Kobayashi, Takashi (Kyoto Univ, Uji, Jpn); Uyeda, Natsuo. *J Cryst Growth* v 84 n 4 Oct 1987 p 589-597.

**082236 DETERMINATION OF DEFECTS IN THE STRUCTURE OF POLYMER MATERIALS.** Sorption methods are the simplest and most accessible methods of nondestructive inspection of materials and components. Penetrant flaw inspection is the most extensively used method. In this method, light- or color-contrast liquid penetrants sorbed by defective areas, cracks, and microcavities are deposited on the surface of the specimen. In this work the authors utilize the sorption of flaw inspection liquids by the specimens of polymer materials in thermostatically controlled gradient column. The selection of the pair of the liquids is determined by the initial density of the polymer and by the number, size, and characteristics of defects. The position of the specimen in the gradient column is fixed using the cathetometer. The variation of the position of the specimen indicates that the

liquid is sorbed without causing swelling of the polymer, and corresponds to the amount of the liquid sorbed by the defective areas. 5 refs.

**082237 CALORIMETRIC DETERMINATION OF HEAD-TO-HEAD DEFECT IN POLY(VINYLIDENE FLUORIDE).** Differential scanning calorimetric analyses were conducted on samples of poly(vinylidene fluoride) polymerized in an autoclave by tributylborane-oxygen by free-radical initiation at low temperature ( $-70^{\circ}\text{C}$ ). The peak melting points and the percent head-to-head defect in each polymer sample were determined by a reported calorimetric method. A commercial sample showed a melting temperature in the range  $157\text{--}162^{\circ}\text{C}$  and a percent head-to-head defect of 7.7%; whereas two experimental samples showed melting temperatures in the range  $172\text{--}179^{\circ}\text{C}$  with a percent head-to-head defect of 4.4 and 4.9%. The calorimetric procedure was modified by reducing annealing times to only 2 h, which saves time and, as shown in this study, avoids thermal polymer degradation. (Author abstract) 15 refs.

**082238 ANALYTICAL FORM OF THE DYNAMOMETRIC CURVES FOR POLYMERS IN ISOTHERMAL CONDITIONS OF DEFORMATION.** A model of the cold stretching of polymers has been devised yielding a differential equation relating the stress in the sample to time or relative deformation. The solution obtained describes the experimental data on uniaxial isothermal stretching of polymers and also relaxation of the stresses after arrest of deformation. Ignoring the process of generation and development of the zone of the oriented conversion in the sample the main process determining the form of the dilatometric curve in isothermal conditions of development of deformation is the orientation of the polymer. The proposed model allows one with the aid of numerical methods of solution to investigate the whole dynamometric curve in the traditional terms of polymer mechanics. (Author abstract) 9 refs.

Lukovkin, G.M. (Lomonosov State Univ, Moscow, USSR); Volynskii, A.L.; Bakeyev, N.F. *Polym Sci USSR* v 28 n 6 1986 p 1396-1402.

**082239 ORIGINAL METHOD FOR STUDYING THE TENSILE DRAWING BEHAVIOUR OF POLYMERS BY INFRARED SPECTROSCOPY AT HIGH-STRAIN RATES.** This communication deals with the description and experimentation of an original method for studying the molecular processes of deformation in polymers by means of infrared spectroscopy under high-speed drawing conditions. The equipment is based on the model of an industrial drawing bench which involves the pulling of a continuous tape or yarn between two sets of feed rolls and draw rolls, in combination with a Fourier Transform Infrared spectrometer. Preliminary light-polarized measurements concerned with a linear low density polyethylene have been undertaken. Well-resolved infrared spectra are reported for a sample drawn at a take up velocity  $V_d = 39\text{m/min}$ , with a draw ratio  $\lambda = 7.8$ . (Author abstract) 20 refs.

Dupuis, J. (Univ de Lille 1, Villeneuve d'Ascq, Fr); Seguela, R.; Sombret, B.; Legrand, P.; Rietsch, F. *Polym Bull (Berlin)* v 18 n 4 Oct 1987 p 323-327.

**082240 DEFORMATION RECOVERY BEHAVIOUR OF A SOLID POLYMER AFTER TENSILE YIELDING. II. EFFECT OF TEMPERATURE.** The

deformation recovery behavior of an amorphous polymer after large tensile deformation is studied at different temperatures. The effect of three parameters other than temperature has been pointed out in previous works. The data presented indicate that the influence of all parameters, including temperature, on recovery behavior can be related to the residual stress,  $\sigma^*$ , at the beginning of recovery test. This suggests to plot the recovery versus time curves, relative to different sets of parameters including temperature, by means of the same normalizing groups which were adopted, thus shifting all curves towards a single master curve. (Edited author abstract) 14 refs.

Rizzo, Giovanni (Univ of Palermo, Palermo, Italy); Spadaro, Giuseppe. *Polym Bull (Berlin)* v 18 n 4 Oct 1987 p 361-368.

**082241 ROLE OF STRUCTURAL FACTORS IN RESISTANCE TO INELASTIC DEFORMATION OF NETWORK POLYMERS.** From analysis of the activation parameters of deformation determined in the transitional region on continuous loading the author examines the special aspects of deformation of network polymers on compression in different relaxation regions. The possibility of qualitative prediction of the prolonged deformative properties on the basis of the activation parameters found in short-term tests is demonstrated. The author's findings indicate that the elementary acts of the process of deformation are identical for different loading regimes. The deformations corresponding to  $\sigma_1$  and the start of sharp increase in the rate of creep are close in the case considered. It is known that the deformation criterion of long-term strength is based on the independence of the value of limiting deformation from the test conditions. (Edited author abstract) 15 refs.

**082245 METHOD OF DESCRIBING KINETIC CURVES FOR THE ACCUMULATION OF CRAZES IN THE DEFORMATION OF AMORPHOUS POLYMERS UNDER CREEP CONDITIONS IN ADSORPTION ACTIVE MEDIA.** An equation describing the kinetics of accumulation of crazes as a function of time or deformation under creep conditions is proposed. The equation is based on the assumption of the threshold character of craze appearance and the presence of a craze growth rate function. The expression obtained is a good description of the kinetic curves for the accumulation of crazes and the limiting number of crazes as a function of the stress. (Author abstract) 8 refs.

**082246 DEFORMATION OF SEMICRYSTALLINE POLYMERS VIA CRYSTAL-CRYSTAL PHASE TRANSITION.** A classification is given of flexible, semicrystalline polymers based on the early stage deformation behavior in the solid state. The criteria of each category are discussed with experimental evidence from the literature on 17 polymers. The central aim of this classification is to point out the possibility of ductility induced during deformation. The understanding of the induced ductility in a given semicrystalline polymer suggests a systematic route to optimize solid-state deformation processes for achieving high draw ratios. (Author abstract) 65 refs.

**082247 EFFECT OF THERMAL HISTORY ON THE DEFORMATION MECHANISMS OF 2,6-DIMETHYLPOLY(PHENYLENE OXIDE).** Stress-strain relationships of 2,6-dimethyl poly(phenylene oxide) (2,6 MPPO) was established simultaneously with optical micrographic examination as a function of thermal history. Films ( $5\text{--}7\text{ }\mu\text{m}$ ) were solvent cast and annealed below their glass transition and melting point. As-cast film showed ductile behavior associated with shearband formation, whereas thermally treated material exhibited marked embrittlement; the slower it cooled the more brittle it became. Thermally treated material showed mixed mode deformation; crazing and shearbanding. The correlation between the deformation mechanism and its solid state structure was studied using differential scanning calorimetry, wide angle x-ray diffraction, and density measurement. (Author abstract) 16 refs.

**082248 DEFORMATION-DEPENDENT PROPERTIES OF POLYMER NETWORKS CONSTRUCTED BY ADDITION OF CROSS-LINKS UNDER STRAIN.** Final network properties (elasticity and structure factor) are calculated for polymer networks which are constructed by addition of cross-links at a series of deformations. It is shown that the m-network hypothesis is valid as an interpretation of the free energy of deformation. A simple modification of this hypothesis allows for a similar interpretation of the structure factor. (Edited author abstract) 10 refs.

**082249 KINETIC MODEL FOR TENSILE DEFORMATION OF POLYMERS. 2. EFFECTS OF ENTANGLEMENT SPACING.** A new kinetic model for deformation of polymers, introduced previously, is employed to study the orientational and morphological changes that occur during tensile drawing of high molecular weight polyethylene. In the model, the polymer solid is represented by a loose network of entangled chains that are tied together through numerous weak (van der Waals) bonds. This study focuses on the effect on the deformation behavior of the entanglement spacing which can be experimentally varied by using solution crystallization techniques. Calculated stress-strain curves are found to be in excellent agreement with experimental results. Apart from quantitatively predicting the stress-strain behavior, the present model also reveals the various morphological changes that are observed in tensile deformation of polymers. (Edited author abstract). 19 refs.

**082251 FREE RADICALS GENERATED IN POLY(4-METHYLPENTENE-1) BY MECHANICAL DEGRADATION.** Structure of free radicals formed by mechanical degradation in poly(4-methylpentene-1) was elucidated from an analysis of EPR spectra. Radicals with free valency localized on tertiary carbon atoms either in the main chain or in the side group were identified. The radicals of the first type assume different conformations in the crystalline and liquid phase. Simple hydrocarbons (methane etc.) have been found in the products of low-temperature mechanical degradation of poly(4-methylpentene-1). (Author abstract) 8 refs.

**082252 THERMAL DECOMPOSITION OF POLY(ARYL ETHER KETONES).** Thermogravimetry has been used to study the isothermal decomposition of poly(aryl ether ether ketone) and poly(aryl ether ketone) and the kinetics of decomposition established from the evolved volatiles. Both products and measured activation energies were consistent with a chain scission process occurring at ether and carbonyl linkages. The volatile decomposition products were analysed by mass spectroscopy and were found to contain various oligomers together with phenol and dibenzofuran. The volatile products were richer in hydrogen than the parent polymers, at the expense of a carbon-like insoluble residue. The degradation products are accounted for in terms of random chain scission and transfer reactions. (Author abstract) 2 refs.

**082254 KINETICS OF MECHANICAL DEGRADATION IN MELTS UNDER MODEL CONDITIONS AND DURING PROCESSING OF POLYMERS - A REVIEW.** The mechanodegradation of polymers in melts has been studied in terms of free radical processes. It is suggested that changes in molecular weight only occur at the chain propagation step. It is shown that the kinetic scheme accounts for the following characteristics: smooth dependence of molecular weight on temperature in model conditions and a sinusoidal dependence in processing, a decrease in the width of the Molecular Weight Distribution function, a quantitative correlation between ruptures and cross links on the one hand and change in double bond concentration on the other and an increase in long-chain branching due to the reaction of chain-side radicals. The effects of processing conditions (oxygen, inhibitor, fillers, type of equipment, etc.) are shown. (Author abstract) 33 refs.

**082255 PHOTO-OXIDATIVE STABILITY OF ELECTRON BEAM AND UV CURED ACRYLATED EPOXY AND URETHANE ACRYLATE RESIN FILMS.** The post-cured photo-oxidative stability of urethane and bisphenol-A epoxyacrylate resins in mixed compositions with triacrylate and amine diacrylate resins are examined using UV and reflectance infra-red absorption spectroscopic techniques. Overall electron-beam cured resin films are more photostable than UV cured films, indicating the high photo-activity of residual photoinitiator in the latter case. Regarding the UV cured systems benzophenone is found to be a more photo-active residual photoinitiator than the benzoyl ester photofragmenting types. Films containing the amine diacrylate resin are more photostable than those containing the triacrylate resin. This stabilizing effect is associated with the oxygen and radical scavenging ability of the terminal amine groups. Photo-yellowing is observed only in resin films containing the amine diacrylate resin and is associated with the formation of unsaturated carbonyl groups. (Edited author abstract) 8 refs.

**082257 IN VIVO DEGRADATION CHARACTERISTICS OF POLY( $\beta$ -PROPIOLACTONE) PREPARED BY RADIATION-INDUCED POLYMERIZATION AT LOW TEMPERATURE.** The polymerization rate of  $\beta$ -propiolactone (PL) by irradiation at  $-78^\circ\text{C}$  in vacuo increased markedly with the irradiation dose of up to 50 kGy and then gradually increased at an irradiation dose of up to 200 kGy. The yields of poly (PL) obtained at irradiation doses of 50 and 200 kGy were 22 and 25%,

respectively. The polymer was shaped into a cylindrical form with high rigidity and density by pressing at 200 kg/cm<sup>2</sup> in a range of 50°C to 75°C. The in vivo degradation of cylindrical specimens was checked by implanting subcutaneously in the back of the male Wistar rats. The data of X-ray diffraction patterns and DSC curves showed that the in vivo degradation is influenced by a change in the crystallinity or by a decrease in the melting point of poly(PL). (Edited author abstract) In Japanese. 11 refs.

**082258 UV DEGRADATION OF POLY[1-(TRIMETHYLSILYL)-1-PROPYLENE] AND EFFECTS OF SENSITIZERS ON THE DEGRADATION.** UV degradation of poly[1-(trimethylsilyl)-1-propylene] denoted as PMSP and effects of sensitizers on the degradation were studied. PMSP was degraded by UV irradiation under air and in vacuo. The rate of degradation was enhanced in a presence of oxygen. The degradation was random chain scission as found from the relationship between the applied dose and the reciprocal of molecular weight of PMSP degraded. PMSP polymerized by NbCl<sub>5</sub> turned out to be more degradable than that polymerized by TaCl<sub>5</sub>. The energy transfer between composite sensitizers plays a role in the sensitization. **082259 DEGRADATION AND STABILIZATION OF POLYMERS.** The main types of degradation are thermal, mechanical, oxidative, radiative, biochemical, high energy and solvent, with strong interconnections among them, not yet fully clarified. This paper describes the more important of these types of degradation, and a look is taken at the possibility of recovering polymers from municipal solid wastes, as a policy of 'prolonging' their utilization in the form of energy. 51 refs.

Maltese, Paolo. *Kem Kem* v 15 n 2 1988 p 115-121.

**082260 POLYMER DEGRADATION DURING COMBUSTION.** A novel driven-rod, radiant pyrolysis technique has been used to study the steady-state linear regression of vertically mounted poly(methyl methacrylate) and polypropylene rods degrading from the top under high-flux, nonflaming conditions that simulate those of combustion. With this technique reliable temperature-depth and oxygen-depth profiles have been obtained and used to calculate the observed mass loss rates and to elucidate the mode of polymer degradation during combustion, respectively. For poly(methyl methacrylate) burning in this rod configuration, condensed phase oxidation is unimportant and the degradation mechanism is similar to that under more conventional slow-heating conditions in the absence of air. In contrast, for burning polypropylene condensed phase oxidation occurs; the lack of oxygen incorporation suggests that the polymer degrades by oxygen-promoted pyrolysis. (Author abstract) 18 refs.

**082262 CATALYTIC SELECTIVITY OF DIAZONIUM TETRAFLUOROBORATE FOR POLYMER DEGRADATION.** Highly reactive photoinitiators afford very sensitive photopolymer systems at the expense of thermal stability. The catalytic selectivity of p-substituted benzene diazonium tetrafluoroborate was studied by using polyacetaldehyde (APA) as a degradable polymer. APA containing p-dimethylaminobenzene diazonium tetrafluoroborate  $[(CH_3)_2NBD]$  photodegraded above 60°C, but did not above 40°C in spite of the actual photodecomposition of  $[(CH_3)_2NBD]$  as detected by UV spectroscopy. The phenomenon was ascribed to the coordination of  $BF_3$ , which was generated from  $(CH_3)_2NBD$ , to the dimethylamino group, since the dimethylamino group and  $BF_3$  work as an electron donor and an acceptor, respectively. Above 60°C,  $BF_3$  coordinated to the dimethylamino group was dissociated to degrade the APA. Photolysis of  $(CH_3)_2NBD$  above 60°C generated free  $BF_3$  to catalyze the degradation. Therefore  $BF_3$  generated from  $(CH_3)_2NBD$  in APA showed catalytic selectivity. (Edited author abstract) 15 refs. In Japanese.

**082264 INVESTIGATION OF THE INFLUENCE OF METAL OXIDES ON THE THERMAL DEGRADATION OF CHLORINE-CONTAINING POLYMERS BY THERMOGRAVIMETRY.** The influence of oxides of zinc, magnesium, antimony and aluminium on the thermal degradations of polychloroprene, chlorinated polyethylene and epichlorohydrin homopolymer has been investigated. The investigations showed that these metal oxides can change the thermal stabilities and degradation processes of chlorine-containing polymers. A considerable acceleration of the dehydrochlorination of these polymers was found in the presence of zinc oxide. (Author abstract) 5 refs.

Kleps, T. (Inst of Rubber Industry, Pol); Piskiewicz, M. *J Therm Anal* v 32 n 6 Nov-Dec 1987 p 1785-1789.

**082265 CATALYTIC DEGRADATION OF POLY(A-METHYLSTYRENE) IN THE PRESENCE OF SILICA-ALUMINA.** Catalytic degradation of poly(a-methylstyrene) in the presence of silica-alumina catalyst was investigated. Volatile main products were cumene (17.8 mol% based on the monomer-unit in sample-feed) and benzene (14.1 mol%) after 1 h reaction at 240°C. Indane skeletons were formed on the chain ends of degraded oligomers. Propylene units were detected on the degraded polymer chains. It was clear from the relationship between the composition of reaction products and scission-number of polymer chains that the catalytic reactions were mainly dephenylation as initiation reaction,  $\beta$ -scission of carbonium ions produced on the main chain, and depolymerization by  $\beta$ -scission of chain-end carbonium ions. (Edited author abstract). 20 Refs. In Japanese.

**082266 THERMAL DEGRADATION OF SOME POLYMERS BASED ON ETHYLENE GLYCOL DIMETHACRYLATE.** Thermogravimetric analysis and pyrolysis in combination with gas chromatography were used to study the thermal behavior of some cross-linked polymers of ethylene glycol dimethacrylate. The investigated polymers show a complex thermal degradation mechanism. The complexity of the reaction increases together with increase of the ethylene glycol chain in the macromolecule and with increase of the pyrolysis temperature. At low temperature, the thermal decomposition products of analyzed polymers are mainly the constituent monomers. At high temperatures, besides the monomer, other decomposition products are formed as a result of thermal cracking reactions, i.e. secondary reactions of decomposition and recombination. (Author abstract). 17 Refs.

Cascaval, C.N. (Petru Poni Inst of Macromolecular Chemistry, Iasi, Rom); Hurdud, N.; C Poinescu, Ig. *J Therm Anal* v 34 n 1 Jan-Feb 1988 p 311-317.

**082267 DEGRADABLE POLYMERS. IV. DEGRADATION OF ALIPHATIC THERMOPLASTIC BLOCK COPOLYESTERS.** Three block copolymers of poly(ethylene succinate) and poly(tetramethylene glycol) with about 20, 54, and 59 mol% polyether have been prepared and subjected to hydrolytic degradation at 37°C. The sample containing 59 mol% showed drastic changes in the properties after 3 months of degradation, whereas the other samples exhibited only minor changes. The tensile strength was completely lost, the molecular weight had decreased to 7% of the original value, and the crystallinity (measured as heat of fusion) had more than doubled. IR and  $^1H$ -NMR analyses showed that the rates of release of the different polymeric blocks varied throughout the period of hydrolytic degradation. (Edited author abstract). 15 Refs.

**082268 CONVERSIONS OF POLYMERS WITH A SYSTEM OF CONJUGATED BONDS UNDER THE INFLUENCE OF COMPLEX METATHESIS CATALYSTS.** It is shown that polymers with a system of conjugated bonds, in particular, polyphenylacetylene on complex catalysts based on  $WCl_6$  and  $Re_2O_7$  undergo degradation a consequence of which is fall in MM (Molecular Mass) (approx. 10 times) with widening of the MD of the polymer. Enrichment of the polymer with saturated aliphatic groups when the reaction is run in the presence of heptene-1 and also inhibition of the reaction on addition of trimethylvinylsilane indicate that the process studied involves carbene active centers and is a metathesis reaction. This work also opens the way to the use of the reaction of metathesis and comethathesis for modifying the CBPs. (Author abstract). 13 Refs.

**082269 DEGRADATION OF SYNTHETIC POLYMERS: APPLICATION OF SOME PYROLYSIS METHODS IN AN INVESTIGATION OF THE DEGRADATION BEHAVIOUR OF IONOMERS CONTAINING METHACRYLATE SALT UNITS.** Three commercial ionomers, comprising a zinc ion and two sodium ion derivatives of ethylene-methacrylic acid copolymer have been studied; the corresponding homopolymers, polyethylenes, sodium polymethacrylate and zinc polymethacrylate have also been examined under the same experimental conditions as a basis for comparison. Infra-red spectra of the ionomers indicate the presence in the chains of COOH groups as well as the carboxylic salt structure. Thermogravimetry, differential scanning calorimetry and thermal volatilization analysis (TVA) are the pyrolysis methods which have been used. The last of these techniques gives the greatest amount of information, since it provides access to each of the various product fractions. (Edited author abstract) 13 refs.

**082270 ROLE OF METALS AND METAL-DEACTIVATORS IN POLYMER DEGRADATION.** The interaction between metals or metallic compounds and polymers is inevitable in the practical use of polymeric articles, and the stability of the polymers is often modified by these materials. Furthermore, the effect of the metallic compounds on the degradation of the polymers is extremely complicated, and is influenced by various factors. This contribution deals with the possible role of metals or metallic compounds in the degradation of polymers, and this is followed by some typical examples of degradation by metallic compounds, mostly commercial pigments and transition metal compounds of stearic acid and acetylacetone, in typical commercial polymers. Recent studies of the inhibition of the copper-catalyzed thermo-oxidative degradation of polyolefins by deactivators, both commercial reagents and novel products, are discussed. (Author abstract) 40 refs.

**082272 STUDY ON DIPOLE MOMENTS OF MACROMOLECULES. I. APPARATUS FOR DIELECTRIC MEASUREMENTS AND DIPOLE MOMENT OF POLY(p-METHOXYSTYRENE).** A three-terminal cell for the dielectric measurement of liquid was made and the cell capacitance was determined using a capacitance bridge. The accuracy of the dielectric constant measurement with the apparatus was examined by measuring standard materials such as benzene and cyclohexane. The mean square dipole moments of poly(p-methoxystyrene) in benzene were determined by accurate measurements of dielectric constants on the polymer dilute solutions and the values were estimated according to two procedures, i.e., one based on Debye and Halverstadt-Kumler equations (DHK method) and the other on Guggenheim and Smith equations (G-S method). The average dipole moments per repeat unit  $\mu$  were obtained as 1.214 (25°C) and 1.221 (40°C) by the DHK method and 1.204 (25°C) and 1.209 (40°C) by the G-S method (in debye unit). The slight disagreement in  $\mu$  values obtained by two different procedures was interpreted as arising from differences in assumptions used in the DHK method and the G-S method. (Author abstract) 28 refs.

**082273 MULTIPLE DIELECTRIC RELAXATIONS IN SOLID POLYORGANOPHOSPHAZENES.** Dielectric properties of solid films of poly(dichloro phosphazene) (PCPN), poly(diphenoxy phosphazene) (PPPN), and poly(difluoroethoxy phosphazene) (PFPPN) were studied.

ied in the frequency range from 0.1 to 100 kHz. PCPN exhibited only one relaxation peak (named as  $\alpha$  process), while PPN and PFPN exhibited two loss maxima ( $\alpha$  and  $\beta$ ) in the dielectric loss  $\epsilon''$  curve within the temperature range between 90 and 460 K. The  $\alpha$  process for the each sample was seen just above its glass transition temperature  $T_g$ , while the  $\beta$  relaxation was observed only for PPN and PFPN in the region far below their  $T_g$ . This result indicates that the  $\beta$  process is due to rotation of the side groups. Based on the simplest two site model, we estimated the amplitude of the rotational oscillation of the side groups and the energy difference between the two sites. (Edited author abstract) 20 refs.

## Differential Thermal Analysis

**082277 DIFFERENTIAL SCANNING CALORIMETRY OF POLYMER GLASSES: CORRECTIONS FOR THERMAL LAG.** In differential scanning calorimetry (d.s.c.), a peak in the specific heat capacity is observed during the heating stage, occurring at a temperature  $T_p$  which depends upon both the cooling and the heating rates. For a fixed ratio of these rates, such intrinsic cycles yield heating isobars of identical shape, but shifted along

the temperature scale by an amount which depends upon the heating isobars of identical shape, but shifted along the temperature scale by an amount which depends upon the heating (or cooling) rate. The invariance of the peak shape, and in particular the peak width, is shown to provide a means of correcting d.s.c. data for thermal lag on heating. Experimental data for a low molecular weight polystyrene, when corrected for thermal lag in this way, are shown to agree with the predictions of the kinetic model for structural recovery. An analytical treatment of heat transfer in the d.s.c. cell is also described, and the theoretical results are compared with the experimental data. (Edited author abstract) 18 refs.

**082278 THERMAL ANALYSIS OF POLYAMIC ACID-FURYL ALCOHOL COMPOSITIONS.** Polyamic acid (PAA), feryl alcohol (FA) and their mixtures in different ratios were investigated by DTA. The effects of the solvent and the component ratio on the thermal characteristics of the final products were estimated. It was shown that when the PAA-FA composition is heated, PAA is the initiator of the polymerization of FA, and the interaction in the system is profoundly affected by the component ratio and the temperature. The existence of an interaction between the components of the system was confirmed by TG, IR and NMR spectroscopy. (Author abstract) 8 Refs.

**082279 INTERACTION VIA DIFFUSION OF POLYMER CRYSTALS IN GROWING SPHERULITES.** Previous calculations of how diffusion ranges should be averaged when polymer molecules of various lengths are segregated at crystal growth fronts have been extended. Crystals of acicular or lamellar habit are addressed directly, necessarily using more approximate methods, and earlier conclusions regarding appropriate averaging are reaffirmed. Results also lead to a better understanding of why crystalline texture in polyethylene spherulites appears to scale with the averaged diffusion range at crystallization temperatures within regime II but not at higher temperatures within regime I. (Author abstract) 6 refs.

**082282 POLYMER DIFFUSION IN MELT BLENDS OF LOW AND HIGH MOLECULAR WEIGHT.** Forward recoil spectrometry (FRES) was used to measure the tracer diffusion coefficient  $D^*$  of deuterated polystyrene (d-PS), of molecular weight 255,000 daltons, into a matrix blend of high and low molecular weight polystyrene (PS), as a function of the volume fraction  $\Phi$  of the high molecular weight polymer. The low molecular weight PS, 10,000, was too short to entangle, whereas the three different PS's of high molecular weight  $P = 20,000, 000, 250,000$ , and 93,000 blended with the low molecular weight sample were well above the entanglement molecular weight  $M_e$  of the melt. **082283 INTERRELATION OF SORPTION, DIFFUSION AND ADHESION IN EPOXIDE POLYMERS OF DIFFERENT TOPOLOGY.** The effect of crosslink density of epoxide polymers on diffusion and sorption of organic solvents was studied. An increase in crosslink density leads to a change in the mechanism of polymer plasticization by the solvent. The reduction of joint strength of an assembly epoxide polymer/aluminum results from prevailing diffusion of the low-molecular-weight compound along the boundary of the system, where the crosslink density is lower. Principles involved in the formulation of cleansing liquid mixtures for removing polymers from solid surfaces are discussed. (Author abstract) 12 Refs.

**082285 SYNTHESIS AND PROPERTIES OF NEW NON-AQUEOUS DISPERSION POLYMERS.** New block copolymers of a non-aqueous dispersion type which had both hydrocarbon-soluble and -insoluble segments and were soluble or dispersible in non-aromatic solvents were synthesized with polymeric peroxides. Poly(2-ethylhexyl methacrylate-block-methyl methacrylate) is an example. A polymerization process to prepare stable dispersions of low viscosity and high solid content was established by selecting appropriate monomers, molecular weights of block polymer, and solvents of appropriate solubility parameters. It became possible to prepare non aqueous dispersion polymers which have high content of insoluble polymer segment and high solid content in dispersion. (Edited author abstract) 12 refs. ## Dispersions

**082286 POLYDISPERSITY EFFECTS IN POLYMER SELF-DIFFUSION MEASURED BY SMALL-ANGLE NEUTRON SCATTERING.** The small-angle neutron scattering (SANS) method for measuring the self-diffusion coefficient  $D$  has been analyzed for effects of polydispersity in degree of polymerization for the case of linear polymers diffusing by reptation. Polydis-

persities corresponding to  $M_w/m_n = 1.0-10$  were considered. It is shown that in all cases a meaningful effective diffusion coefficient  $D_e$  can be obtained from the short time recovery of the SANS intensity. This quantity  $D_e \leq 1.3 D(M_w)$ , where  $D(M_w)$  is the diffusion coefficient of a monodisperse polymer having molecular weight  $M = M_2$ . The method relies on SANS intensities extrapolated to zero scattering angle; realistic extrapolation is shown to give rise to quite acceptable errors on the order of 0.05  $D_e$ . **082287 IMMUNOCHEMICAL STUDIES WITH POLYMER MICROSPHERES CONSISTING OF HYDROPHILIC/HYDROPHOBIC COMPONENTS PRODUCED UNDER VARIOUS EMULSION POLYMERIZATION CONDITIONS.** Three kinds of polymer microspheres consisting of styrene and 2-hydroxyethyl methacrylate components were produced by different emulsifier-free emulsion polymerization methods. They had similar surface hydrophilicities, based on saturating adsorption of an anionic emulsifier. By using these microspheres, the colloidal stability at the step of sensitization with antibodies, security of immunologic agglutination and suppression of nonspecific agglutination, which are main fundamental requirements for immunomicrospheres, were studied. The results were very different among the three kind of microspheres. The differences were assumed to be caused by the differences in the surface characteristics of microspheres. (Edited author abstract) In Japanese. 18 refs.

**082289 INFLUENCE OF DOPANT ION AND SYNTHESIS VARIABLES ON MECHANICAL PROPERTIES OF POLYPYRROLE FILMS.** Oxidized, conductive poly(pyrrolylium anion) films [poly(pyrrolylium) = PP+ where there exists about one cation per three pyrrole rings] have been prepared electrochemically in an effort to study the effect of counteranion structure and preparation conditions on the composition, order (crystallinity), and mechanical properties of the films. The counteranion principally employed was p-toluene-sulfonate (OTs<sup>-</sup>). It was found that the amount of OTs<sup>-</sup> incorporated increased with increasing potential during synthesis, suggesting a parallel increase in the extent of oxidation of the polymer. Mechanical testing of the same films demonstrated that the ultimate tensile strength decreased as the electrode potential and current density during synthesis increased. **082292 EFFECT OF DOPING ON THE CRYSTALLINE STRUCTURE OF POLYPARAPHENYLENE.** The authors observed an increase of about 50% in the diameter of the fibres of Kovacic PPP after AsF<sub>5</sub> doping. This suggests penetration of the dopant molecules inside the fibre. This is confirmed by the lowering of the crystallinity and the disappearance of a distinct crystallite texture. The nature of the crystalline phase responsible for the diffraction pattern is not clear and is likely to be of paracrystalline character. An intercalation model could account for the new diffraction peaks as an average cell. 11 refs.

**082293 EFFECT OF POLYMERIZATION ANION ON ELECTROCHEMICAL PROPERTIES OF POLYPYRROLE AND ON Li/LiClO<sub>4</sub>/POLYPYRROLE BATTERY PERFORMANCE.** Electrochemical doping-undoping kinetics of electropolymerized polypyrrole (PPy) and the charge-discharge characteristics of Li/LiClO<sub>4</sub>/PPy battery were found to show an interesting dependency on the kind of anions used for the preparation of PPy film. The relationship between the doping charge (anodization charge estimated from cyclic voltammogram) of PPy film and the polymerization potential revealed that the optimum potential for getting the largest doping capacity depends strongly on the kind of anions. The optimum potential for PF<sub>6</sub><sup>-</sup> and CF<sub>3</sub>SO<sub>3</sub><sup>-</sup> formed PPy films was 0.32V vs. Ag/Ag<sup>+</sup>. On the other hand, ClO<sub>4</sub><sup>-</sup> formed PPy film had the largest doping charge at 0.84V preparation over an examined potential range (0.30-0.84V). (Edited author abstract) 15 refs.

**082294 THERMODYNAMICALLY REVERSIBLE UPTAKE OF ELECTRICALLY ACTIVE DOPANTS IN CONDUCTING POLYMERS: IODINE IN POLYTHIOPHENE.** The absorption isotherm, at 50°C, for I<sub>2</sub> vapor in polythiophene film is determined by both absorption and desorption measurements and can be reproduced (repeatedly) after I<sub>2</sub> has been fully desorbed. There is no obvious hysteresis, and the evidence in favor of the achievement of reversible thermodynamic equilibrium with respect to the distribution of the electrically active dopant I<sub>2</sub> between the conducting polymer and the vapor phase, is overwhelming. The experimental results of

this paper contradict the widespread notion that doping processes in conducting polymers cannot be brought to thermodynamic equilibrium. Since analyses of molecular level phenomena, based on equilibrium studies, are both more reliable and easier to perform than analyses involving nonequilibrium studies, it is important to discover other conducting polymer systems that exhibit similar reversible equilibria. (Edited author abstract) 11 refs.

**082295 THEORETICAL ANALYSIS OF PROTONIC ACID DOPING OF THE EMERALDINE FORM OF POLYANILINE.** The measurements of J.C. Chiang and A.G. MacDiarmid on the pH dependence of the 'equilibrium' proton doping of the emeraldine form of polyaniline are considered. A statistical thermodynamic theory is developed for the proton adsorption isotherm, based on a strong repulsive interaction between protons on nearest-neighbor nitrogen atoms, and, also, the pH dependence of the pK<sub>a</sub> for adsorption is calculated. The derived isotherm exhibits the necessary 'saturation' at the 50% doping level, while the derived pK<sub>a</sub> exhibits the necessary 'constancy' at high pH. (Edited author abstract) 10 refs.

**082296 DOPING BEHAVIOUR OF POLY(2,5-PYRIDINEDIYL).** Poly(arylene)s such as poly(p-phenylene) and poly(2,5-thienylene) having  $\pi$ -conjugation along the polymer chain are converted into electrically-conducting materials by oxidation (p-doping) or reduction (n-doping). The doping behaviour of the polymer is considered to reflect the chemical and physical properties of the recurring unit of poly(arylene). The results described indicate that poly(2,5-pyridinediyl) is easily reduced to give the electrically-conducting n-doped material, but oxidation is not easy. This is in sharp contrast to the reducing and oxidizing behaviour of the five-membered heterocyclic polymer, poly(2,5-pyrrolylene). (Edited author abstract). 17 Refs.

**082298 ROLE OF DOPANT ENVIRONMENT IN ELECTRET-FORMING POLYMERS.** Poly-(2-vinylpyridine), P2VP, poly-(2-vinylquinoline), P2VQ, and their 4-vinyl isomers have been synthesized and chemically doped under different conditions. The materials have been characterized by a variety of techniques to establish synthesis-structure-doping correlations, which seem helpful clues in analyzing current work on their electric properties. In particular, the dopant environment within one or more inequivalent sites inside the polymeric lattice plays an important role in transport mechanisms. To study this effect properly, it proved necessary to relate doping conditions to the structure of the polymer (molecu-

lar and supramolecular, macro- and micro-structure), which in turn depends on synthetic conditions. (Edited author abstract) 13 refs.

**082301 PRODUCTION OF ORIENTED POLYMER TUBE BY THE DIE-DRAWING PROCESS.** Three modes of drawing are described. Tubes can be drawn axially with a simultaneous large reduction of diameter, which is useful for making clad and filled products with high axial stiffness. Tubes can be drawn axially with little change of bore and this gives uniform products with increased axial stiffness and improved barrier properties. A novel way of pressure-testing such tubes is described. Tubes can also be produced with a combination of axial draw and hoopwise expansion. These products have a biaxially oriented structure, and consequently show improvements in hoop ductility. (Edited author abstract) 8 refs.

**Education**

**082304 POLYMERS - AN EXPANDED SCIENCE?** Just over 14 years ago the Macro Group UK surveyed for the first time the teaching of macromolecular science in the chemistry departments of universities, polytechnics and colleges of higher education in the UK and found disquieting features. A second survey has recently been done which reveals that there has been a significant expansion in macromolecular science teaching in the polytechnics and colleges of higher education but much less of a change in the universities. Particularly worrying is a marked reduction in the number of macromolecular science 'specialists' in university chemistry departments, which is likely to inhibit growth in this important area of applied chemistry even further. (Author abstract) 3 refs.

**Elasticity**

**082305 ULTRASONIC MEASUREMENTS OF THE ELASTIC MODULI OF ULTRADRAWN POLYOXYMETHYLENE.** We have employed an ultrasonic method to measure from  $-40$  to  $60^\circ\text{C}$  the five independent elastic moduli  $C_{11}$ ,  $C_{13}$ ,  $C_{33}$ ,  $C_{44}$ , and  $C_{66}$  of polyoxymethylene with draw ratio  $\lambda$  from 1 to 26 prepared by continuous drawing under microwave heating. The elastic moduli are controlled by three major factors: molecular orientation in the crystalline regions, fraction of noncrystalline taut tie molecules, and void content. The steep rise in the axial extension modulus  $C_{33}$  and axial Young's modulus  $E_0$  with increasing draw ratio results from the alignment of chains in the crystalline blocks and an increase in the number of disordered taut tie molecules. Below the  $\gamma$  relaxation, these two factors also give rise to a slight decrease in the transverse extensional modulus  $C_{11}$ , Young's modulus  $E_{90}$ , and shear modulus  $C_{66}$ . (Edited author abstract) 19 refs.

**082307 TEMPERATURE-TIME DEPENDENCE OF THE ELASTIC MODULUS FOR ORIENTED POLYMERS.** An experimental study was made of the

temperature time dependence of the elastic modulus  $E$  for 30 oriented polymers differing in chemical structure. The formula derived to describe the temperature-time dependence of the elastic modulus is given. It appears from the experimental results that a common basis underlies the nature of processes of relaxation of the elastic modulus on the one hand and fracture of a loaded polymer body on the other hand. It should be noted that the magnitude of the mechanical stress developing in a body in the process of determination of  $E$  Elastic Modulus particularly when acoustic and dynamic methods are used is small, like the duration of their influence. This means that there is insufficient time for fracture processes to develop to the point where they would need to be taken into account in an analysis of the results obtained. **082311 SINGLE-TRAP-CONTROLLED TRANSIENT HOPPING PROCESS IN MOLECULARLY DOPED POLYMERS.** Time-of-flight measurements on molecularly doped polymers have revealed that the tran-

sient current shapes change from being virtually non-dispersive to highly dispersive (featureless) and back to non-dispersive as the shallow trap concentration is increased from 0 to approximately 1 mol%. The shallow traps were introduced into the molecularly doped system by mixing the charge-transporting molecule with small amounts of another transporting molecule having a significantly lower ionization potential. The results support the model of F. Schmidlin for single-trap-controlled transport. Based on this model, the attempt-to-escape frequency and the activation energy for escape from the trap are found to be approximately  $4 \times 10^{12} \text{ s}^{-1}$  and 0.56 eV, respectively. (Author abstract) 11 refs.

**082312 PROPERTIES OF  $\text{SbCl}_5$ -DOPED PPP/PPS COMPOSITES I. ELECTRICAL CONDUCTIVITY STUDY.** In this set of two papers the electrical and surface mechanical properties for sintered polyparaphenylene/polyparaphenylene-sulfide (PPP/PPS) composites, in a wide range of compositions, are reported. The present paper deals with a conductivity study of these materials. PPP, before and after annealing at  $400^\circ\text{C}$ , was used as a potential conductive component. It is shown that these  $\text{SbCl}_5$ -doped sintered composites undergo a discontinuous transition from non-conductor to conductor at 20% PPP. The surface of the sintered materials and the dopant distribution across the thickness were characterized by scanning electron microscopy and energy dispersive X-ray analysis respectively. Morphological aspects are discussed in the light of conductivity measurements. In addition, the electrical stability after storage of the composites in air and in dry nitrogen atmosphere is examined. Finally, the influence of the annealing behavior of the PPP component upon the limiting conductivity level is highlighted. (Author abstract) 21 refs.

**082313 CHEMICAL OXIDATIVE POLYMERIZATION OF SOME BENZODIPYRROLES TO ELECTROCONDUCTIVE MATERIALS.** Conductive polymers obtained from pyrrole and thiophene derivatives have received special attention because of their electrical properties and environmental stability. The authors report on the oxidative polymerization of benzodipyrroles in MeOH at room temperature, with anhydrous  $\text{FeCl}_3$  (three moles per mole of substrate); in each case black, insoluble and infusible powders precipitate from the reaction medium. Composition and conductivity data of the obtained polymers are reported. Although no structural data are available to identify the positions at which the polymerization occurs, the fact that the benzodipyrroles undergo electrophilic substitution at the  $\beta$ -positions of the pyrrole rings, suggests that these same sites might well also be involved in the oxidative coupling. 8 refs.

**082314 INFLUENCE OF IONIC DOPANTS ON THE CONDUCTIVITY OF ELECTROCHEMICALLY SYNTHESIZED POLYPYRROLE.** Comparison of elemental analytical, XPS and SIMS data allows a semi-quantitative assessment of the dopant and oxidation states of polypyrrole synthesized using a variety of potentials and electrolyte concentrations. Studies of polypyrrole grown in aqueous solution indicate, contrary to previous reports, that a maximum in the conductivity is observed for films grown close to the oxidation-reduction potential and in agreement with out previous observations on organically grown polypyrrole. Treatment of electrochemically synthesized polypyrrole with sodium hydroxide leads to a reduction in the electrical conductivity by three orders of magnitude and similarly the addition of hydrochloric acid causes an increase in the electrical conductivity by several orders of magnitude. (Edited author abstract) 11 refs.

**082316 CONDUCTIVITY MEASUREMENTS OF ELECTRODEPOSITED POLYPYRROLE.** Thick, freestanding, flexible films of polypyrrole have been prepared from propylene carbonate solutions of pyrrole monomer containing tetra-ethyl ammonium p-toluene sulphonate electrolyte. The conductivity of the films was found to vary with orientation of the sample, deposition temperature and time. Conductivities of up to  $338.4 \text{ S cm}^{-1}$  were attained with samples prepared at  $0^\circ\text{C}$ . XRD analyses have revealed a difference in structure with sample orientation which affects the conductivity of the material significantly. (Author abstract) 25 refs.

**082317 SELECTIVE 1,2-POLYMERIZATION OF TRIETHYLSILYLBUTADIENE AND ITS ELECTRICAL CONDUCTIVITY.** Triethylbutadienyldisilane was polymerized selectively at the 1, 2-position by a Ziegler-Natta catalyst. The polymer obtained was soluble in non-polar organic solvents, and the average molecular weight of 4600 was found by vapor pressure osmometry. It showed an electrical conductivity of  $32.2 \times 10^{11} \text{ S cm}^{-1}$  and  $6.0 \times 10^{11} \text{ S cm}^{-1}$  without and with  $\text{I}_2$  doping, respectively. Bulky silyl groups on the polymer were eliminated by tetrabutylammonium fluoride treatment to give poly(ethynyl acetylene). The conductivity of poly(ethynyl acetylene) was  $6.4 \times 10^{-8} \text{ S cm}^{-1}$  without doping. It was considerably improved by heat-treatment at temperatures higher than  $600^\circ\text{C}$ . Heat-treatment at  $800^\circ\text{C}$  for 2 h attained to provide  $7.8 \times 10^{-1}$  without doping. A partial acene structure was suggested in the heat-treated poly(ethynyl acetylene). (Author abstract) 9 refs.

**082318 PRESSURE DEPENDENCE OF ELECTRICAL CONDUCTIVITY IN POLYPYRROLE.** The electrical conductivity as a function of pressure to about 1.1 GPa is determined for p-toluenesulfonate-doped polypyrrole at two different doping levels and also for tetrafluoroborate-doped polypyrrole. A second-order polynomial is found to fit the observed data better than either of the existing models. The polynomial is of the form  $\sigma(P) = aP^2 + bP + \sigma(0)$ . (Author abstract) 8 refs.

**082319 XPS STUDIES OF CHEMICALLY SYNTHESIZED POLYPYRROLE-HALOGEN CHARGE TRANSFER COMPLEXES.** Simultaneous polymerization and doping of pyrrole have been carried out in the presence of a halogen electron acceptor, iodine ( $\text{I}_2$ ) or bromine ( $\text{Br}_2$ ), in aqueous dispersion or in acetonitrile at

0 to  $4^\circ\text{C}$  to give PPY- $\text{I}_2$  and PPY- $\text{Br}_2$  charge transfer complexes. X-ray photoelectron spectroscopy (XPS) has been used to evaluate the degree of oxidation of the polypyrrole nitrogen atoms. The XPS results show that in both cases, not all the halogen dopants are available for oxidation. In the case of PPY- $\text{I}_2$ , as much as 34% of the total iodine present has undergone ring substitution in the polymer chain. (Edited author abstract) 20 refs.

Chan, H.S.O. (Nat'l Univ of Singapore, Kent Ridge, Singapore); Munro, H.S.; Davies, C.; Kang, E.T. *Synth Met* v 22 n 4 Feb 1988 p 365-370.

**082320 INTRINSIC CONDUCTIVITY OF CONDUCTING POLYMERS.** Because the charged dopant ions are spatially separated from the quasi-one-dimensional conduction path in conducting polymers, resistive back scattering is suppressed. In the case of high molecular weight and relatively few  $\text{sp}^3$  defects, even relatively weak interchain coupling is sufficient to avoid one-dimensional localization; this leads to coherent transport with a mean free path that is limited by either the mean separation between chain imperfections or by phonon scattering. The authors emphasize that although their results were presented in the context of polyacetylene, the conclusions are general and should be applicable to the entire class of conducting polymers. (Edited author abstract) 20 refs.

Kivelson, S. (Univ of California at Santa Barbara, Santa Barbara, CA, USA); Heeger, A.J. *Synth Met* v 22 n 4 Feb 1988 p 371-384.

**082321 THERMOPOWER AND CONDUCTIVITY OF METALLIC POLYANILINE.** The temperature dependences of conductivity and thermopower of the metallic polyaniline salts are presented, along with the dependence of conductivity on chemical potential and doping level. As the degree of protonation increases, the sign of the thermopower changes from positive to negative. Although the structure of the polyaniline is known to be complex, we propose a model which can interpret the thermopower sign-cross-over behavior is a relatively simple way. (Author abstract) 19 refs.

**082322 EFFECT OF THE OXIDATION CONDITIONS ON THE CHEMICAL POLYMERIZATION OF POLYANILINE.** Chemical polymerization of aniline with four oxidizing agents ( $\text{NH}_4)_2\text{S}_2\text{O}_8$ ,  $\text{H}_2\text{O}_2$ ,  $\text{K}_2\text{Cr}_2\text{O}_7$  and  $\text{KIO}_3$  was studied in HCl solutions. It was established that the redox potential of the oxidizing agent is not a dominant parameter. Products of similar quality have been obtained with  $(\text{NH}_4)_2\text{S}_2\text{O}_8$ ,  $\text{K}_2\text{Cr}_2\text{O}_7$  and  $\text{KIO}_3$ . However,  $\text{KIO}_3$  seems the most convenient, because it yields good quality samples in a wide range of polymerization conditions. (Author abstract) 5 refs.

**082323 OBSERVATION OF ELECTROCHEMICAL POLYMERIZATION PATTERN OF CONDUCTING POLYMER AND ITS INTERPRETATION BY FRACTAL DIMENSION.** Characteristic growth patterns of conducting polymers prepared by the electrochemical polymerization method have been found to be strongly dependent on the polymerization conditions and undergo dramatic change during their growth. In polypyrrole, three types of growth one-, two- and three-dimensional growth, have been observed depending on the condition. These are discussed in terms of fractal dimension. (Author abstract) 14 refs.

**082324 ELECTROCHEMICAL BEHAVIORS OF POLYPYRROLE, POLY-3-METHYLTHIOPHENE, AND POLYANILINE DEPOSITED ON NAFION-COATED ELECTRODES.** Anodic polymerization of pyrrole, 3-methylthiophene, and aniline at Nafion-coated electrodes gives conducting polymer-Nafion composite films. The composite films show better reversibility in the film redox process than conducting polymer films alone, owing to different charge compensation mechanisms in the redox reaction; electrolyte cations are involved in the redox process of the composite films, whereas electrolyte anions are in the ordinary conducting polymers. The fast kinetics of the redox process of the composite films are effectively demonstrated by an improvement of the polypyrrole electrochromic response and by the efficient utilization of stored charge by the composite film electrodes. (Author abstract) 22 refs.

**082325 DYNAMIC PERCOLATION IN AN INSULATOR-CONDUCTOR COMPOSITE: POLYETHYLENEOXIDE-POLYPYRROLE, AS STUDIED BY A.C. CONDUCTIVITY MEASUREMENTS.** We report measurements of a.c. conductivity in the insulator-conductor polymeric system polyethylenoxide-polypyrrole for frequencies between d.c. and 9.4 GHz. The a.c. conductivity is shown to follow the general law  $\sigma(\omega) \approx \omega^x$  for frequencies higher than a critical frequency. For every concentration of polypyrrole a frequency region has been found where the predictions for anomalous diffusion in three-dimensional fractal percolating clusters ( $x = 0.6$ ) can be considered as fulfilled. The calculated critical frequencies exhibit a dependence on the concentration of the conducting polypyrrole additive as expected by the theory through the expression for the correlation length of the random resistor network of Miller and Abrahams. This model was previously employed to describe the d.c. behavior of these composite systems. (Author abstract) 17 refs.

**082326 CLASS OF CONDUCTING POLYMERS HAVING NONCONJUGATED BACKBONES.** Having a conjugated backbone is usually considered to be a necessary condition for a polymer to be electrically conducting. This paper will demonstrate that, in association with appropriate substituents, a nonconjugated polymer system may also become electrically conducting. The chemical constitution, electrical transport, and optical properties of the conducting complexes of a specific class of such nonconjugated systems are discussed in this paper. The details of the origin of conductivity for such nonconjugated systems are studied for a specific example, 1,4-cis-polyisoprene, which is considered to be a prototype for this class. This is the first time that conducting complexes having isolated double-bond structures are reported. (Author abstract) 15 refs.

**082327 BROMINE TREATMENT OF POLY[ $\alpha$ -(5,5'-BITHIOPHENEDIYL)BENZYLIDENE] (PBTB) AND POLY[ $\alpha$ -(5,5'-BITHIOPHENEDIYL)-p-ACETOXY-BENZYLIDENE] (PBTAB): A COMPLEX REACTION.** In this paper we report that the reaction of both PBTB (2) and PBTAB (3) with bromine vapor depends on the phase (solid-gas versus solution-gas), and the product of either reaction condition is not the simple dehydrogenated product reported before but a brominated material containing covalently bonded as well as ionic halogen. Once the bromination product of 2 is reduced with hydrazine to remove the dopant bromide, it exhibits a bandgap of 1.53 eV (presumably dehydrogenated, partially brominated material) and not 0.83 eV as claimed before. Based on experimental evidence the purported brominative dehydrogenation of methine-

linked polythiophenes does not lead to simple products but is a complicated reaction, leading to products which are probably dehydrogenated but which also contain bromine bonded covalently and ionically. 10 refs.

**082328 BAND STRUCTURES OF POLYFULVENE AND RELATED POLYMERS. A MODEL FOR THE EFFECTS OF BENZANNULATION ON THE BAND STRUCTURES OF POLYTHIOPHENE, POLYPYRROLE, AND POLYFULVENE.** At the level of Hückel theory, polyfulvene (PF) has a valence band/conduction band degeneracy much like that seen in polyacetylene. Higher levels of theory remove the degeneracy, but the band gap ( $E_g$ ) is predicted to be significantly smaller than analogous structures such as polythiophene and polypyrrole at a fulvenoid geometry. An alternative geometry, which we have termed quinoid, is also conceivable for PF, and it is predicted to have a much larger  $E_g$ . The effects of benzannulation to produce analogues of polyisothianaphthene (3) have been evaluated. We propose a new model for such structures based on conventional orbital-mixing arguments. Several of the proposed structures have quite interesting properties, which suggest that they are excellent candidates for conducting polymers. (Author abstract) 20 refs.

**082329 MOBILITY OF CHARGE CARRIERS IN POLYMERS.** The mobility of the charge carriers has been investigated for a number of polymers by the flight-time method at room temperature. It is shown that in PS it is the holes that are mobile and in PETP the electrons. The absolute values of the drift mobility measured in the polymers indicated in the regime of dispersion transport are low even in strong electric fields approximately  $10^2$  V/m and higher. The results are well consistent with the data on the effect of additives on the non-steady radiation electrical conductivity of the polymers studied. (Edited author abstract) 6 refs.

**082332 CONDUCTIVE POLYMERS BASED UPON RIGID-ROD ULTRAHIGH-MODULUS MACROMOLECULES. ELECTROCHEMICAL DOPING OF POLY(P-PHENYLENEBENZOBIS-**

**THIAZOLE-2,6-DIYL) (PBT).** The authors provide the first evidence that PBT can be electrochemically doped and undoped, either as thin coatings or as extruded, highly oriented free-standing films and fibers, to yield an electrically conductive polymer. A  $1.5 \times 0.75 \times 0.002$  cm strip of heat-treated uniaxial PBT film can be reversibly doped within two hours at  $-2.10$  V versus SCE (in TBABF<sub>4</sub>/THF using pressure contacts) to yield a flexible, copper-black, air-sensitive film. As doping proceeds, the black coloration is observed to spread most rapidly in the orientation parallel to the fiber extrusion (chain axis) direction. Similar observations obtain for heat-treated PBT fibers. These results demonstrate that a rigid-rod, ultrahighmodulus macromolecule such as PBT can be electrochemically doped and that the resulting electronic structure can support facile charge transport. Equally noteworthy is the observation that the doping process can be effected for such a polymer in a highly ordered and closely packed crystalline microstructure. 14 refs.

**082334 ELECTRICAL CONDUCTIVITY BEHAVIOR OF POLY(ETHYLENE OXIDE) IN AQUEOUS ELECTROLYTE SOLUTIONS.** The electrical conductivity of poly(ethylene oxide) of different molecular weights in 0.1 M KCl electrolyte solution has been measured in the temperature interval from 0 to 55°C. The data have been interpreted on the basis of the Looyenga equation for heterogeneous systems, found to apply with good approximation also for other transport properties. The hydration number deduced from these measurements has been estimated to be lower than that reported elsewhere. Its dependence on temperature, however, supports the occurrence of a cloud point temperature which agrees with the values observed in similar systems. These findings are consistent with the measured activation enthalpy values, which are very similar to that of the pure solvent, indicating that poly(ethylene oxide)-water interactions give rise to a structure that would form a rather open hydrogen-bonded network. (Author abstract) 22 refs.

**082335 EFFECT OF PHASE SEPARATION ON DIELECTRIC RELAXATION AND THE ELECTRICAL CONDUCTIVITY OF THE BUTADIENE-STYRENE RUBBER-POLYETHYLENEIMINE SYSTEM.** It is shown that precipitation in the system butadiene-styrene rubber-polyethyleneimine occurring in the region of low concentrations of polyethyleneimine (0.2 wt percent) corresponds to the minima in the concentration functions of the specific volumetric resistance  $\rho$  and the dielectric constant  $\epsilon$ . For 3 wt. percent polyethyleneimine and higher anomalous rise in  $\rho$  is observed as compared with that of the initial rubber accompanied by heavy increase in low frequency dispersion of  $\epsilon$  and the appearance of additional maxima in the thermogram of the currents of thermostimulated depolarization due to the

multiplicity of the relaxational processes in polyethyleneimine and the effects at the phase-matrix boundary. (Author abstract). 3 Refs.

**082336 SEEING THROUGH SYNTHETIC METALS.** Cheap, lightweight, durable and easy to make: these are the principal characteristics expected of polymer conductors that endear them to the electronics industry. Practice has not yet matched theory, but developments discussed at a recent meeting suggest that there are grounds for hoping that polymers will replace metals as conductors in the next century. In particular, new, nearly transparent polymers have been synthesized that require less energy to excite electrons into the conducting state. Although these have lower conductivities than other polymers at present, they offer greater promise and are easily processed. The usual polymers for these studies, polyacetylene, polythiophene, polypyrrole and polypara-phenylene, are formed by electrochemical or chemical polymerization of the monomer units. By mechanically aligning the polymer chains of polyacetylene, conductivities as high as  $10^3 \text{ Scm}^{-1}$  have been achieved, comparable to that of copper ( $10^6 \text{ Scm}^{-1}$ ).

**082337 HIGH-PERFORMANCE, ELECTRICALLY CONDUCTIVE POLYMERS.** Three methods have been used to obtain most conductive polymeric materials. With the first method, macroscopic pieces of conducting materials such as metal flakes or carbon black particles are incorporated into polymeric matrices to form conducting composites. The second method involves the addition of either electron donor or acceptor dopants to highly conjugated systems. The third method involves modifying the intrinsic bulk properties of polymers by pyrolysis. The author focuses on pyrolysis as a method for producing conductive materials. He discusses the thermal conversion of a new high-temperature phthalonitrile resin. The synthesis and process ability of electrically conducting compositions are examined along with the conversion of the polymer into a conductive material. 18 refs.

**082342 OPTICAL INVESTIGATIONS OF CONJUGATED POLYMERS.** Conjugated polymers, with delocalized  $\pi$ -electron systems along the polymer chain, show high electronic mobilities along the chains and can behave as semiconductor or, when appropriately doped, as metals. As such, they form an important class of materials for the study of electronic engineering at a molecular level. There are some important differences between these polymeric materials and conventional, inorganic semiconductors which are discussed here. Firstly, charges added to the polymer chain cause a local reorganization of the  $\pi$ -electron bonding, and are localized to form polaron-like states. Secondly, charge transport is inherently anisotropic, with easy motion along chains and slower motion across chains. Some experimental work that has been carried out on well oriented films of these materials that illustrate these aspects of their behaviour is reported. (Author abstract) 51 refs.

**082343 D.s.c., ELECTRICAL CONDUCTIVITY, AND n.m.r. STUDIES OF SALT PRECIPITATION EFFECTS IN PPO COMPLEXES.** Differential scanning calorimetry (d.s.c.) and electrical conductivity measurements of poly(propylene oxide), PPO, complexed with the salts NaI and KSCN are reported. In addition,  $^{23}\text{Na}$  n.m.r. measurements on PPO-NaI ( $x = 8$ ), both at ambient and elevated pressure (2kbar), have been performed. The d.s.c. data clearly indicate that the salt precipitates out of the complexes at about  $85^\circ\text{C}$  for NaI and  $60^\circ\text{C}$  for KSCN. These effects are manifested by a dramatic departure of the conductivity from Vogel-Tammann-Fulcher (VTF) behaviour, and a relatively sharp drop in mobile  $\text{Na}^+$  concentration, as deduced from n.m.r. measurements, above about  $80^\circ\text{C}$ . (Edited author abstract) 5 refs.

## Electric Field Effects

**082344 ELECTROOPTICAL EFFECTS IN COMB-LIKE LIQUID CRYSTALLINE POLYMERS.** The mechanism of the action of an ac field on comb-like LC polymers of the cholesteric type is discussed. The combination of cholesterol- and cyanobiphenyl-containing units in the copolymers provides for helical twisting of supermolecular structure, and enables structural rearrangement to occur in the copolymers in the presence of an ac field. The effect of field untwisting of the cholesteric helix has been discovered. The phase transition induced by the field is interpreted as a transition from cholesteric to nematic type ordering. The polymer structure of the liquid crystals (LCs) makes its own contribution, determining both the type of structural transitions and their kinetics. (Author abstract). 8 Refs.

**082345 RELAXATION PHENOMENA AND ELECTRICAL FLUCTUATIONS IN NONCRYSTALLINE POLYMERS.** A study has been made of electrical fluctuations in PVC, PS and PMMA in the temperature region relating to  $\alpha$  and  $\beta$  relaxation processes. Activation energies of the corresponding relaxation transitions and the intervals in keeping with their appearance have been determined. The state of structural disorder of the studied polymers leads to the manifestation of excessive electrical fluctuations during release of molecular mobility of the various kinetic units. (Author abstract) 16 refs.

**082346 EVALUATION AND CHARACTERISATION OF CHEMICALLY MODIFIED POLYMERS AS SECONDARY ELECTRON EMITTERS.** Measurements of secondary electron emission coefficient and surface work function  $\phi$  are reported for polyacrylonitrile (PAN) and polytetrafluoroethylene (PTFE) in the virgin and chemically modified forms. A single pulse method was used for SEE measurements and a retarding field method for estimating the work function. Doping of PTFE with alkali metals (Na and Li) and pyrolysis of PAN at  $300^\circ\text{C}$  led to an increase in the surface conductivity. The processing of the surface effectively increased the SEE yield in these polymers. Electrical conductivity and XPS results were used to explain the chemical structures of modified polymers. (Author abstract) 27 refs.

**082347 ELECTROACTIVE CHARGE TRANSFER POLYMERS FROM ANODIC COUPLING OF DIBENZO-CROWN ETHERS: PART III, INTRINSIC REDOX PROPERTIES AND PRELIMINARY USE AS ELECTRODE MODIFIERS.** The intrinsic electrochemical properties of the poly(dibenzo-crown ethers) have been investigated. Thus, five different redox states have been pointed out and a detailed analysis of the doping and dedoping processes has been performed. Furthermore, a short account of these polymers as electrode modifiers is presented. (Author abstract) 16 refs.

**082348 PYROELECTRIC AND PIEZOELECTRIC PROPERTIES OF POLYMER COMPOSITES.** Composites of a polymer (PE, PVDF) and the powder of the ferroelectric ceramic ZLT-19 have been

obtained by hot pressing. The pyroelectrical and piezoelectrical coefficients of the composites depending on the volumetric content of the ferroelectric ceramic within the limits 20-60% and the conditions of polarization have been investigated. These properties of the composites are influenced not only by the heterocharges of the residual polarization of the ferroelectric ceramic but also the homocharges localized at the separation boundary of the two phases. (Edited author abstract) 8 refs.

**082349 INTERCHAIN COUPLING IN CONDUCTING POLYMERS: ANISOTROPIC FIELD THEORY.** The effect of interchain coupling of parallel chains of conducting polymers is investigated with the help of a continuum model. Ground state properties and the kink wall excitation are discussed. It is found that the one-dimensional gap is decreased through a renormalization of the electron-phonon coupling constant and that the mid-gap state for a single kink is broadened to a band. (Author abstract) 11 Refs.

Fesser, K. (Univ Bayreuth, Bayreuth, West Ger). *Synth Met* v 25 n 1 Jul 1988 p 1-9.

**082350 EFFECT OF THERMAL HISTORY ON ELECTRICAL FLUCTUATIONS IN POLYMERS.** Thermal treatment of polymers changes the intensity of electrical fluctuations. The position of the maximum in fluctuation voltage in the region of the  $\alpha$ -relaxation process shifts to higher temperatures in annealed but to lower temperatures in quenched samples of poly(methyl methacrylate). Annealing of PMMA not only shifts the  $\beta$ -relaxation to higher temperatures, but also changes the character of the process, and these phenomena are clearly reflected in the intensity of electrical fluctuations. (Author abstract) 9 Refs.

**082351 FREE TRANSITION PHENOMENA AND ELECTRICAL BIREFRINGENCE IN THE ISOTROPIC PHASE OF LIQUID CRYSTALLINE POLYMERS HAVING MESOGENIC GROUPS IN THE SIDE CHAIN.** The electrical birefringence (Kerr effect) in the isotropic phase of thermotropic liquid crystalline comb-like polyacrylic polymer having cyanobiphenyl groups in the side chains is studied. The presence of pretransition effects over several degrees before the temperature of transition into the nematic state in both its equilibrium electrooptical properties and in relaxation phenomena is established. On the basis of a comparison of the electrooptical properties of the polymer and its low molecular weight analogues, conclusions are arrived at on the mechanisms of motion of the polymer chain responsible for the electrical birefringence. Two mechanisms of the Kerr effect dispersion of various types and having different relaxation times and different relaxations with the temperature are observed. (Author abstract) 15 Refs.

**082352 DISCUSSION MEETING: PHYSICS AND CHEMISTRY OF UNCONVENTIONAL ORGANIC MATERIALS.** This conference proceedings contains 26 papers. Topics covered are: charge carrier generation and transport in polyvinyl carbazole; kinetics of geminate pair recombination in polyvinylcarbazole; configurational dynamics of doped glasses and polymers; impurities in organic glasses; light-induced hole transfer; low-temperature phase of the organic conductor; conducting polymers; new conducting polymers; electrochemically prepared radical salts; microwave conductivity in iodine-doped organic conductor; Knight shift in organic conductor; pyroelectricity of solid aromatic compounds; properties of unsymmetrically substituted diacetylenes; ferroelectric

liquid crystals; phase transitions of aromatic radical cation salts; conducting polymers; polymeric phthalocyanines; and, single crystals from optically active diacetylenes and polydiacetylenes. All papers are indexed and abstracted separately. Technical and professional papers from this conference are indexed and abstracted with the conference code no. 10583 in the Ei Engineering Meetings (TM) database produced by Engineering Information, Inc.

**082353 CHARGE CARRIER GENERATION AND TRANSPORT IN POLYVINYL CARBAZOLE: A MODEL SYSTEM FOR POLYMERIC PHOTOCONDUCTORS.** The problem of electron-hole separation in polyvinylcarbazole (PVK) is discussed, based on new 'time of flight' data, covering a time range from 10 nanoseconds to about 10 minutes. The experimental data are analyzed with the aid of the Onsager theory of electron-hole recombination and yield an Onsager radius  $r_0$  of  $18 \pm 2$  Å. Due to the high sensitivity of the method, it is possible to reproduce the low field regime of the Onsager recombination scheme. There are still sizeable deviations between the theoretical and the experimental quantum yields in the midfield regime. These differences do not enter into the determination of the  $r_0$ -value to a great extent because  $r_0$  shows a weak logarithmic dependence on the extrapolated low and high field values of the charge carrier yields. This work is pertinent to xerography and electro-printing. (Edited author abstract) 28 Refs.

**082354 KINETICS OF GEMINATE PAIR RECOMBINATION IN POLYVINYL CARBAZOLE.** Recombination of geminate electron hole pairs (GP) in polyvinylcarbazole (PVK) has been investigated by (i) monitoring the decay of delayed luminescence (DL) following pulse excitation with 4.02 eV photons at temperatures between 20 K and 294 K and (ii) Monte Carlo computer simulation. It is found that the decay of the GP reservoir obeys at  $t \rightarrow 0$  law with  $s$  being close to unity and exhibiting small yet systematic variations depending on temperature and time domain. DL extends up to seconds even at 294 K delineating GP lifetimes accordingly long. It is concluded that recombination kinetics is controlled by both the intrinsic energetic disorder of the bulk hopping sites, i.e., the carbazole groups, and by intermediate trapping at presumably incipient carbazole dimers. (Edited author abstract) 31 Refs.

**082355 ELECTRICAL PROPERTIES OF POLYMERS PREPARED FROM IODO-(4-NITROPHENYL)ACETYLENE.** Iodo-(4-nitrophenyl)acetylene was thermally polymerized at 400°C. Chemical analysis, mass, IR and UV spectroscopy showed that the polymers are built up by polyacene units resulting from crosslinking and intramolecular cyclization of linear oligomers. Iodine is largely lost during polymerization, leading to in situ doping of the polymers. The temperature dependence of the dc conductivity,  $\sigma_{dc}$ , can be represented by  $94 \sigma_{dc} = \sigma_0 \exp[-(T_0/T)^{1/4}]$ . The thermopower shows small positive values, slightly increasing with increasing temperature. The ac conductivity,  $\sigma_{ac}$ , exhibits a strong frequency dependence of the form  $\sigma_{ac} = A\omega^s$  with  $s=0.63$ . The electrical behavior of the polymers is explained in the framework of a variable-range hopping model. (Edited author abstract) 7 Refs.

**082357 HUMIDITY-SENSITIVE AND WATER-RESISTIVE POLYMERIC MATERIALS.** Four types of polymers with pyridinium groups were prepared and their electrical properties as humidity sensors were studied. The polymers are quaternized vinylpyridine and styrene copolymers, partially quaternized polyvinylpyridine, polytetrafluoroethylene grafted with quaternized polyvinylpyridine and polyvinylpyridine crosslinked with dibromobutane. The latter two polymers showed excellent water resistivity as well as a sensitivity to humidity. (Author abstract) 16 Refs.

**082358 FORMATION AND ELECTROCHEMISTRY OF POLYFLUORENE IN AMBIENT TEMPERATURE IONIC LIQUIDS.** Polyfluorene films were deposited on platinum, tungsten, and glassy carbon electrodes by the anodic oxidation of the monomer in ambient temperature molten salts consisting of a mixture of aluminum chloride and 1-methyl-3-ethylimidazolium chloride. The polymer films are conductive in the oxidized state and nonconductive when reduced. The collection efficiency measured by rotating ring-disk voltammetry melts suggests that two protons per monomer are released during the polymerization process for both polyfluorene and polypyrrole formation. The polyfluorene films obtained in these molten salts are more stable and their electrochemical behavior less complicated than those prepared in acetonitrile. (Author abstract) 27 Refs.

**082360 ELECTROLYTE EFFECTS ON THE SWITCHING REACTION OF POLYANILINE.** This report describes the electrochemical behavior of polyaniline prepared in aqueous solution with various acid electrolytes. Electroactive polyaniline with two different cyclic voltammograms, i.e., with and without the additional peak at 500 mV, can be produced by controlling the current densities during the preparation. The oxidation reaction is coulombically reversible, and the rate depends on the acidity of the solution but is independent of the nature of the counter anion. In solutions more acidic than 0.1M, the charge is linear with time in the initial period. In  $10^{-3}$ M acid solutions, the charge has a  $t^{1/2}$  dependence. The films are also electroactive in nonaqueous solvents,

and voltammograms with well-defined waves result when the solution contains both organic salt and protic acid electrolyte. (Edited author abstract) 35 refs.

**082362 LASER INTERFEROMETRY OF THE ELECTRODEPOSITION OF POLYPYRROLE ON A POLYCARBAZOLE ANODE: BILAYER CONDUCTING ELECTRODES.** The electrodeposition of an electronically conducting layer of polypyrrole on a polycarbazole anode was performed galvanostatically in N,N-dimethyl formamide containing tetra-n-butyl ammonium perchlorate as the electrolyte in the medium. The deposition was followed by holographic interferometry and laser interferometry to estimate the diffusion layer. The bilayer polymeric material was examined by scanning electron microscopy and it revealed structural features, i.e., the polycarbazole film appears fibrous in form. The electrodeposition was also conducted by the potential sweep technique in the above medium. (Edited author abstract) 13 refs.

**082363 CATALYTIC ELECTROSYNTHESIS OF CONDUCTING POLYMERS.** A novel catalytic electrodeposition of several kinds of conducting polymers in aqueous solutions is described. The anodic deposition potentials of pyrrole, N-methylpyrrole and aniline were shifted in the negative direction by 140-200 mV in the presence of tiron (4,5-dihydroxy-1,3-benzenedisulfonic acid) as a catalyst in the reaction mixture. The catalytic depositions of polypyrrole and polyaniline, and the compositions of the produced films, were investigated. The conductivity of the catalytically prepared free-standing polypyrrole films was smaller than that of the directly prepared films. This one-step process was used to produce films holding anions (such as carboxylates) which cannot play the role of dopant in the direct oxidation of the monomers, and thus to simplify the preparation of drug-loaded conducting polymers for a drug release device. (Author abstract) 12 refs.

**082365 ELECTRONIC STRUCTURE AND PHOTO-INDUCED STRUCTURE CHANGE OF POLYDIACETYLENE CRYSTAL.** A self-consistent calculation of the electronic structure is performed for a model polydiacetylene crystal by using the local density functional method. The wave function and the energy eigenvalues of excitons are calculated and the third order susceptibility is shown to be enhanced by the large oscillator strengths of the excitons. A mechanism of photo-isomerization of polydiacetylene crystals is proposed. (Author abstract) 21 refs.

Tanaka, H. (Univ of Tokyo, Tokyo, Jpn); Inoue, M.; Hanamura, E. *Solid State Commun* v 63 n 2 Jul 1987 p 103-107.

**082366 ELECTRONIC PROPERTIES OF POLY(1-METHYLCYCLOHEXA-1,3-DIENE-2,3-DIYL-5,6-DIYLDIENE-5-METHYLIDYNE-6-NITRIL).** Poly(1-methylcyclohexa-1,3-diene-2,3-diyl-5,6-diylidene-5-methylidene-6-nitril) (PMQ), prepared at four different temperatures from 250 to 385°C, was studied. There is 1 spin per 200 to 400 repeats. The temperature dependence of unpaired spin concentration for PMQ4 condensed at 385°C implies that a phase transition from magnetic disorder to order may occur near 74 K. PMQ3 condensed at 345°C was doped with nitrosyl hexafluorophosphate (NFP) and iodine. Iodine intercalated between the layers but hexafluorophosphate did not. EPR studies suggest that NO<sup>+</sup> oxidized the polymer to produce charged spinless species. (Edited author abstract) 46 refs.

**082367 AB-INTO≡ SELF-CONSISTENT FIELD THEORY FOR THE TREATMENT OF INTERFACE BETWEEN TWO DIFFERENT QUASI-ONE-DIMENSIONAL CHAINS.** The solution of the problem how to treat an interface between two quasi-one-dimensional polymers has been formulated combining Dyson's equation with the mutually consistent field (self-consistent field solutions for the change of the bulk states of the polymers and for the extraband 'interface' states) method. A numerical procedure for the implementation of an appropriate program (which needs as input only the ab initio self-consistent field crystal orbital solutions of the two infinite periodic polymers as well as some cluster calculations of the interface and its neighbors at both sides) is outlined. The necessary program is under development. (Author abstract). 16 Refs.

Ladik, Janos (Friedrich-Alexander-Univ Erlangen-Nuernberg, Erlangen, Engl). *Prog Surf Sci* v 26 n 1-4 1987 p 135-143.

**082368 MODEL CALCULATION OF POLYMER HETEROSTRUCTURES.** The energy bands and corresponding eigenfunctions of polymer heterostructures are calculated on the basis of a Hückel-like theory. The underlying physical models are coupled conjugated polymer systems consisting (i) of polydiacetylene (PDA)-polyacetylene (PA) units and (ii) of cis-trans PA units. Discrete split-off states within the energy gaps are analyzed with respect to their energies and localization of the corresponding wavefunction. Criteria for one-dimensional molecular quantum well structures and molecular electronic devices are discussed. A model describing the electronic transport is developed. (Author abstract). 15 Refs.

## Emulsions

**082372 ELECTROPHORETIC, DYNAMIC, AND STATIC LIGHT SCATTERING ON CHARGED POLYMER EMULSIONS.** Light scattering studies on dispersions formed by phase separation of a polymer-solvent-non-solvent mixture show that the dispersions comprise charged droplets of the polymer-rich phase. The charge number is not large, and data on the electrophoretic-scattering and the dynamic scattering in the absence of an external electric field are both consistent with distribution of charge among the droplets. Data on the dependence of the static scattering on concentration and scattering angle show that the droplets are also disperse in radius. The data are discussed in terms of an interaction potential among the charged droplets relating the electrostatic interactions to the charge number and radius of the droplets, and the ionic strength of the solvent. (Author abstract) 22 refs.

## Esterification

**082373 TRANSESTERIFICATION REACTIONS IN MOLTEN POLYMERS.** The transesterification reaction of molten ethylene and vinyl alcohol copolymers (EVA), in presence of paraffinic alcohols and basic catalysts, leads to high conversion of the ester groups to secondary alcohol in both discontinuous and continuous processing equipment. Various kinds of alcohols and two different catalysts were used. Sodium methoxide is a powerful catalyst for the equilibrated transesterification

reaction, but the authors also observed side reactions, such as cross-linking with low-molecular-weight alcohols and hydrolysis of the catalyst followed by partial saponification of the EVA. Kinetic studies were performed in the presence of dibutyltin dilaurate, an efficient catalyst without any side reactions. The solubility of the main alcohol reagents was verified by diffusion measurements. The general reaction scheme and the related kinetics, corresponding to a homogeneous system, lead to a fair evaluation of the rate constants. (Edited author abstract) 10 refs.

**082375 DECREASE IN THE ETCH RATE OF POLYMERS IN THE OXYGEN AFTERGLOW WITH INCREASING GAS FLOW RATE.** In this paper we report the variation of the etch rate of polymers in the afterglow of a radio frequency discharge in oxygen as a function of total flow rate in the range 2-10 cm<sup>3</sup> (STP)/min. The measurements were made at ambient temperature with the O(3P) concentration held essentially constant. We report results on three polymers: cis-polybutadiene, a polybutadiene with 33% 1,2 double bonds, and a polybutadiene with 40% 1,2 double bonds. We have observed that the etch rate of these polymers decreases significantly with increasing flow rate, strongly suggesting that the vapor-phase products of polymer degradation contribute to the degradation process. (Author abstract) 11 refs.

**082376 INSTRUMENTATION DEVELOPMENT OF SENSING MODES OF BUBBLE MOTION OF A BLOWN-FILM PROCESS.** We have developed instrumentation using an internal-bubble pressure transducer with a data acquisition system to sense LLDPE bubble stability on a commercial blown-film line. Real-time bubble instability was also recorded using a video camera at a speed of 30 frames/s. The pressure signal analyzed using a fast-Fourier-transform (FFT) computer program to determine the frequency of bubble oscillation. Since bubble instability often consists of large-scale oscillation and bubble flutter, and both motions affect gauge and layflat uniformity, the pressure signal was decomposed to determine the frequency of each oscillation mode. To obtain a stable bubble, the amplitudes of both oscillation modes must be reduced to a minimum. Initial results indicated that the trace of the pressure can provide a warning to the stability of a blown-film process. (Edited author abstract) 8 refs.

Huang, T.A. (Mobil Chemical Co.). *Adv Polym Technol* v 8 n 1 1988 p 69-75.

**082377 PRODUCTION OF ULTRAHIGH-MODULUS LIQUID-CRYSTAL POLYMER RODS.** Since thermotropic liquid-crystal polymers (LCPs) consist of rigid backbone molecules, high-modulus/high-strength fibers with a high degree of molecular orientation can be easily fabricated by a melt-spinning process. However, LCP strand properties decrease with an increase in the strand diameter. A less oriented structure is formed in the core of a strand due to molecular relaxation as well as less orientational stresses imposed on the LCP molecules in the core area. In this note we report another approach to producing high-modulus/high-strength LCP rods. Rods were extruded using conical converging die. 9 Refs.

**082378 FLEXED PLATE IMPACT TESTING OF POLY(ETHER SULPHONE). PART III FLOW GEOMETRY EFFECTS.** Tests on various sample shapes moulded from poly(ether sulphone) show that the response to an excess energy impact may be brittle failure, ductile failure or mixed mode failure, depending on the geometrical features and the associated flow geometries at or near the point of impact. Flow irregularities and local anisotropies caused by the overall flow geometry can be as detrimental to the toughness as conventional stress concentrators are. The results, which are unlikely to be unique to poly(ether sulphone), imply that the procedures currently followed for the evaluation of impact resistance are generally insufficient for their purpose since materials are likely to differ in their susceptibility to embrittlement. (Author abstract). 5 Refs.

**082379 FAILURE-MECHANISM MAPS FOR ENGINEERING POLYMERS.** This paper reports on progress in assembling experimental data and simplified theoretical models for the deformation and fracture of engineering polymers into diagrams which summarize their inelastic response to stress. A number of regimes are identified: brittle fracture initiated by crazing or shear-banding; plasticity terminated by ductile fracture; cold-drawing; rubbery and viscous flow; a regime in which deformation is purely elastic; and one in which adiabatic heating influences deformation. Data for a number of commercial polymers (polymethylmethacrylate, polystyrene, polycarbonate, polyisobutylene and an epoxy resin) are fitted to simplified constitutive equations for each regime. The equations are then used to construct diagrams, one for tension and one for compression, which relate strength to temperature T and strain rate  $\dot{\epsilon}$ , over a wide range of these variables. (Author abstract). 79 Refs.

**082380 TOUGHNESS OF A COMPOSITE CONTAINING SHORT BRITTLE FIBRES.** A method is presented whereby various potential contributions to the toughness of a polymer containing short brittle fibers can be quantified. It relies on a model for predicting the cumulative probability distribution of fiber pull-out lengths. The method reveals that toughness increases to a maximum value with increasing fiber length. Good agreement between theory and experiment supports the validity of the approach. (Author abstract) 7 refs.

**082381 MOLECULAR-KINETIC MODEL OF UNIAXIAL TENSION AND COMPRESSION OF HIGHLY ORIENTED POLYMER FIBERS.** A number of special features of the mechanical behavior of high-modulus polymer fibers are associated with a high degree of orientation ordering of the macromolecules comprising these fibers. These special features include, for example, the large increase of the dynamic modulus of elasticity of the fibers during their loading with tensile forces and additional orientation effects in tensile loading. The authors use the simplest model as an example to investigate the conditions of existence of macromolecules of the fiber in the highly oriented state and certain relationships governing tension and compression along its axis. The paper examines a section of an arbitrary polymer chain consisting of N elastic links joined together by hinged consecutive connection; the chain is positioned among similar chains inside the fiber to which the external tensile or compressive force P is applied in the direction of its x axis. 10 refs.

**082382 MODE OF CRACK PROPAGATION IN RUBBER-CRUMB-FILLED POLYMER COMPOSITION.** We have previously reported how rubber crumb modulus and crumb to matrix adhesive affect the performance of rubber-containing soft fillers. The tensile and tear properties of these two-phase elastomer composites were correlated with variations in the tear energy of the matrix and crumb and the adhesive energy. Further, the effect of rubber-crumb loading upon breaking stress and strain of filled polystyrene composites was reported. This work was further extended to an examination of fracture roughness. It is now possible to utilize a simple model to predict the mode of crack propagation for these systems. 13 refs.

**082383 INFLUENCE OF PARTICULATE FILLERS ON THE INDENTATION HARDNESS OF A GLASSY CROSS-LINKED POLYMER.** The indentation hardness of a glassy cross-linked network was decreased to a minimum value by a low volume fraction (0.03 to 0.05) of each of six fillers having rigid particles varying in size and surface. This 'minimum' effect was eliminated after specimens were more highly cross-linked by prolonged exposure to  $\gamma$ -rays. These results are consistent with an earlier suggestion that filler particles act as stress concentrators which may cause increased localized plastic deformation and hence a decreased indentation hardness. In the case of larger particles, morphological evidence of localized plastic deformation was obtained by fractography. (Author abstract) 19 refs.

Haque, Z.U. (Univ of North Carolina, Chapel Hill, NC, USA); Turner, D.T. *J Mater Sci* v 22 n 9 Sep 1987 p 3379-3384.

**082384 CONFORMATION OF MACROMOLECULES IN FILLED POLYMERS.** A split plane densely packed with macromolecules is considered to be an appropriate model for interlayers in filled polymers. The structure of amorphous chains among the filler particles is assumed to be the same as the conformation of isolated Gaussian chains in critical conditions corresponding to

the beginning of adsorption of chains from the solution. In this case the thickness of the boundary layer is comparable with the dimension of the chain in bulk. The chains in the layer are flattened parallel to the filler surface. The number of contacts between the chains and the filler is proportional to  $M^{1/4}$  and decreases with increasing distance between the chains and the surface, while the end-to-end distance does not change monotonously. (Author abstract) 11 refs.

**082385 SELF-TEMPERATURE-CONTROL HEATERS BY GRAPHITE-POLY(ETHYLENE GLYCOL) MIXED SYSTEMS: MECHANISM OF ELECTRICAL CONDUCTION.** The authors have found that graphite-poly(ethylene glycol) mixed systems constitute self-temperature-control heaters and that the self-controlled constant temperatures depend on the molecular weight of the poly(ethylene glycol). The mechanism of self-temperature-control for these systems cannot be explained in terms of volume expansion of the total system, which has hitherto been suggested for the self-temperature-control mechanism for systems such as carbon-rubber mixtures. It is found that the temperature dependence of the electrical resistance in a graphite-poly(ethylene glycol) system corresponds well to that of the dielectric constant in the corresponding pure poly(ethylene glycol) system. This leads to a model by which the mechanism of electrical conduction and self-temperature-control can be explained. The voltage dependence of the electric currents in graphite-poly(ethylene glycol) systems supports this model. (Edited author abstract) 16 refs.

**082386 COMPOSITION DEPENDENCE OF TENSILE YIELD STRESS IN FILLED POLYMERS.** Filled polymers are the simplest type of composite polymeric materials, which consist of a matrix polymer as a continuous phase and a generally inorganic filler dispersed in the matrix. Among the mechanical properties yield stress of the composite ( $\sigma_{yc}$ ) has primary importance, giving information on the maximum allowable load without considerable plastic deformation. A simple model for calculating the composition dependence of this tensile yield stress is presented. 6 refs.

**082387 MOLECULAR MOTIONS IN FILLED POLYDIMETHYLSILOXANES.** Molecular motions in filled polydimethylsiloxanes (PDMS) have been investigated. Frequencies of the most low temperature motions (rotation of  $\text{CH}_3$  groups about the Si-C bond) are scarcely dependent on the filler content. Motions of chain units are severely inhibited in an adsorption layer of thickness approximately 8 Angstrom. Motions of chain fragments adjoining the adsorption layer are also inhibited to some extent. In PDMS with a high loading of filler a fraction of the nonadsorbed units are highly mobile below  $T_g$ , apparently on account of defects in the packing of individual chain fragments. Frequencies of rapid reoriented motions of nonadsorbed units some distance away from filler particles approximate to those of motions in the unfilled PDMS. At the same time slow translational motions of the units are inhibited. (Author abstract) 18 Refs.

**082388 CHARACTERIZATION OF CARBON BLACK FILLED POLYMERS USING SMALL ANGLE X-RAY SCATTERING AND TRANSMISSION ELECTRON MICROSCOPY: A COMPARATIVE STUDY.** This study has shown that small-angle x-ray scattering and transmission electron microscopy produce

similar results for the average agglomerate sizes of carbon black dispersions. These sizes are characteristic of the degree of dispersion present in various materials such as reinforced rubber. In addition to the average sizes, the inner specific surface areas, distribution of particle sizes, and shapes of the agglomerates may be important parameters in determining the ultimate physical properties. The inner specific surface areas and average agglomerate sizes are conveniently determined from SAXS measurements. Detailed information about the agglomerate size distributions and shapes are obtainable from TEM micrographs. 7 Refs.

**082391 SPECTRAL CHANGE OF POLYMER FILM CONTAINING POLY(3-ALKYLTHIOPHENE) WITH TEMPERATURE AND ITS APPLICATION AS OPTICAL RECORDING MEDIA.** A remarkable absorption spectral change has been observed in polymer films containing poly(3-alkylthiophene) with temperature which is explained in terms of the transition of conformation of poly(3-alkylthiophene) in polymer matrix. By quenching the sample from a high temperature, the high-temperature spectrum has been maintained even at room temperature. The spectral change by laser irradiation and its memory have also been confirmed. The applications of these phenomena as optical recording and memory elements are also proposed. (Author abstract) 7 refs.

**082392 STATIC AND DYNAMIC FORCES ACROSS POLYMER LIQUID FILMS.** The author describes some recent results on two different polymeric liquids obtained using the Israelachvili surface force apparatus. In this apparatus the force between two mica surfaces is measured by the deflection of a spring on which one of the surfaces is mounted. By monitoring the transient response of the surfaces to a known displacement of the reference end of the spring, it is possible to measure the drag force which results from viscous coupling between the surfaces. The equilibrium surface force shows a repulsion extending approximately 15 nm, which is nearly ten times the estimated radius of gyration (1.6 nm). Dynamic force measurements show that the polymer melt has a viscosity equal to its bulk value (54 cP) even in very thin films, but the stick boundary conditions apply at a

distance 2-3 nm from each surface. 7 refs.

**082393 PHOTOACOUSTIC MEASUREMENTS OF THERMAL DIFFUSIVITY OF PYROLYZED POLY( $\alpha$ -CHLOROACRYLONITRILE) FILMS.** The thermal diffusivity of poly( $\alpha$ -chloroacrylonitrile) (PCAN) films heat-treated at temperatures from 140°C to 1300°C was measured by a photoacoustic method. Measurements were also made of infrared spectrum and electrical conductivity. The thermal diffusivity of PCAN film did not change by heat-treatment at temperatures below 600°C, but increased above 700°C from a value of  $4 \times 10^{-7} \text{ m}^2/\text{s}$  for the untreated film to a value of  $2 \times 10^{-6} \text{ m}^2/\text{s}$  for the film heat-treated at 1300°C. IR spectra showed that the formation of carbeneous structure becomes evident by heat-treatment above 700°C. This indicates that the increase in thermal diffusivity is due to the development of graphite-like layers. The correlation between the changes in thermal conductivity and electrical conductivity did not fit Wiedemann-Franz's law. It was concluded that the carriers in the PCAN pyrolyzates investigated are not electrons but phonons. (Author abstract) 5 refs. In Japanese.

**Fire Resistance** See ELECTRIC CABLES—Fire Resistance.

**Flame Resistance** See Also PLASTICS, FOAMED—Rigid.

**082394 FIRE TESTING OF POLYMERS.** Fire tests are carried out to determine the fire behaviour of a material or a product. The ultimate use of such a test is to reduce or control the fire hazard of the material or product in its end-use environment. The fire behaviour of a product may be defined in terms of its ignition resistance, rates flame spread, heat release, smoke production and toxic gas generation. These parameters are not fundamental material properties but may be significantly affected by interactions of materials, design and with their end-use environment. The actual fire hazard of a product or material will also involve human and other factors. There are a great many standardised tests to determine the fire performance of materials and products but before selecting a particular test, it is necessary to assess the end-use hazards and also the performance needed to provide the level of safety required. This paper reviews the various tests of fire against a background of material and product applications. (Author abstract) 74 refs.

**082396 THERMAL BEHAVIOUR OF BROMINE-METAL FIRE RETARDANT SYSTEMS.** Chemical reactions which occur on heating fire retardant mixtures of decarboxymodiphenyloxide (DBDPO) with antimony trioxide (AO) or bismuth carbonate (BC) have been studied by means of weight loss, elemental analysis, X-ray diffraction, scanning electron microscopy (SEM) and energy dispersive system (EDS) microanalysis. It has been shown that on rapid heating to 700°C, DBDPO volatilisation competes with debromination by AO or BC leading to volatile  $\text{SbBr}_3$  or  $\text{BiBr}_3$  which are formed by different mechanisms. BC is rapidly transformed into  $\text{BiOBr}$  which gives  $\text{BiBr}_3$  by further debromination of DBDPO. At high conversion (high temperature), this process is in competition with reduction of  $\text{BiOBr}$  to metallic bismuth. In the case of AO slower formation of progressively bromine-rich antimony oxybromides takes place which liberates  $\text{SbBr}_3$  by thermal degradation. (Edited author abstract) 14 refs.

## Flocculation

**082397 MOLECULAR DETAILS OF THE SOLVENT INDUCED FLOCCULATION OF DILUTE STERICALLY STABILISED POLYMER COLLOIDS.** The incipient flocculation behavior of sterically stabilized nonaqueous dispersions has been extensively investigated. These studies have identified the flocculation conditions either visually or using turbidity measurements. Such techniques identify the gross flocculation behavior of the colloid but do not furnish any information about the flocculation process at the molecular level. In this paper, the authors outline fluorescence energy transfer experiments which allow the opportunity to follow the change in conformation of the steric barrier as the solvency of the dispersion medium is varied. It is concluded from such experiments that in dilute sterically stabilized dispersions, the steric barrier collapses in the vicinity of the flocculation point. (Edited author abstract) 11 refs.

**082398 THERMAL EFFECTS IN THE NECKING OF POLYMERS.** A certain fraction of the mechanical work performed on a specimen is converted into heat during necking of plastic material. A method for measuring this fraction is proposed when specimens are drawn in two different surroundings, air and water. Differences in the heat transfer coefficients of these two media influence the temperature rise during necking. The fraction ( $\alpha$ ) of mechanical work converted into heat can be calculated using data determined at only one draw rate. The value of  $\alpha$  calculated for polypropylene is 0.55 and for polyethylene it is 0.48. (Author abstract) 5 refs.

**082399 SPATIAL PATTERNS FORMED BY GROWING TEOS POLYMERS.** Silicon tetraethoxyde (TEOS) monomers are dissolved in a water/ethanol mixture. Through hydrolysis and condensation they aggregate to form branched siloxane polymers; in a few hours these polymers build a gel throughout the solution. The patterns formed by the growing polymers are studied through small angle neutron scattering. In the reaction bath, these patterns result from repulsive interactions,

whose range  $\zeta$  is controlled by the smaller polymers of the bath. In diluted solutions, the patterns give the size  $R_z$  of the largest polymers, which limits the connectivity of the reaction bath. As the polymers recombine, the connectivity length diverges, whereas the interaction length remains microscopic and keeps growing regardless of the gel point. This growth leaves the network with a set of self similar heterogeneities similar to those found in many other gels. (Author abstract) 44 refs.

**082400 EXTREMELY HIGH MOLECULAR WEIGHT POLYMER FORMATION USING A PHOTOINITIATION SYSTEM OF XANTHATE FIXED AT AN ORIENTED BILAYER SURFACE.** The authors show a new polymerizable bilayer system in which a photoinitiator consisting of two long alkyl chains and a xanthate group which are coupled via a glutamate connector is fixed near polymerizable groups in a bilayer matrix. It is shown that when the aqueous bilayer solution and the aqueous poly(sodium styrene sulfonate) separately prepared were mixed, the instantaneous precipitation due to formation of polyanion complex of the polyanion and the cationic bilayer component was observed. Since no precipitate was observed during polymerization for the mixed bilayer systems in spite of the formation of high molecular weight polymers, the resulting polymers would have a suitable conformation for maintaining an aqueous bilayer state. Experiments indicate that extremely high molecular weight polymers can be produced under mild conditions in a bilayer state by taking advantage of the well-defined bilayer surface and fixation of the photoinitiator at the most effective position for initiation. 10 Refs.

## Fractionation

**082402 FRACTIONATION OF SYNTHETIC POLYMERS USING SUPERCRITICAL NITROUS OXIDE.** The use of supercritical fluids for processing of synthetic polymers has recently been receiving considerable attention in the chemical industry. In a previous paper, fractionation of synthetic oligomers using light hydrocarbon supercritical fluids was described. This manuscript reports the use of supercritical nitrous oxide for the fractionation of synthetic polymers according to molecular weight. The authors felt it would be beneficial to briefly describe methods used to fractionate synthetic polymers using supercritical  $\text{N}_2\text{O}$  and to present properties of the resulting fractions. 8 refs.

**082403 EFFICIENCY OF POLYMER FRACTIONATION - A REVIEW.** With respect to molecular masses, polymers are polydisperse. Since many of their properties depend on the distribution of molecular masses, to study this correlation it is necessary to have samples of narrow molecular mass distribution or samples with

accurately defined distribution. In spite of the developmental progress of fast instrumental methods (analytical and preparative gel chromatography) used to determine the molecular mass distribution curve and to obtain higher amounts of fractions of narrow molecular mass distributions, there still exists an interest in classical methods of fractionation. On the basis of a survey of monographs on polymer fractionation, numerous publications and personal experience, this review describes primarily what is an efficient fractionation. Afterwards, factors that affect fractionation efficiency according to the type of effects are given and causes of their action are described. Conditions under which efficient fractional precipitation and fractional solution methods are applied are considered separately. At the end of the review, criteria on the basis of which fractionation efficiency is evaluated are considered in detail. (Author abstract) 81 refs.

**082405 FRACTURE TESTING OF POLYETHER-SULPHONE INJECTION MOULDINGS.** Single-edge-gated injection molded discs of PES have been subjected to three types of fracture mechanisms test. Two methods previously found to give consistent results on other polymers, three-point bending and single-edge notch tension, gave  $K_{Ic}$  values which were questionable: the bend test results were functions of molding depth, while tensile specimens showed evidence of yielding. Fractography indicated that the conditions of plane strain were not fulfilled during crack propagation in these specimens, the fracture surfaces being very rough and the crack fronts highly curved. Accordingly the ASTM compact disc test was adapted as a whole-mold test, since this is particularly suitable for investigating orientation effects and allows stable crack propagation. (Edited author abstract) 16 refs.

**082406 DYNAMIC EFFECTS ON FRACTURE SURFACE FORMATION IN BRITTLE POLYMERS (2ND REPORT, EXAMINATION OF SURFACE MARKINGS).** The dynamic fracture surface formation of PMMA and epoxy was studied. Fracture parameters such as crack velocity  $a$  and crack extension resistance  $R$  were obtained by high-speed photography of fracture caustic images. The density of surface marking was also obtained by examination of the fracture surfaces. Correlations between the density  $\mu$  and the fracture parameters have shown that, although  $\mu$  depends on  $a$  or on  $R$ ,  $\mu$  is not a unique function of one of those parameters. It is found that  $\mu$  has the best correlation with the product  $Ra$ , i.e., dissipated energy per unit crack front and unit time. (Author abstract) 7 refs. In Japanese.

**082408 SLURRY ABRASION OF POLYMERS UNDER SIMULATED SUBMARINE CONDITIONS.** The present study was initiated to gain relevant data on the behavior of some candidate commercial polymers when abraded by typical submarine rock particles. Samples of high density polyethylene, polypropylene, poly(vinyl chloride), poly(methyl methacrylate), Delrin and polytetrafluoroethylene were abraded by slurries of crushed submarine rocks (pillow lava and coral). Comparison tests were made with slurries of quartz abrasives and with a pin-on-disk apparatus using SiC sandpaper. It was found that the various polymers tested showed the same general ranking independent of the abrasive used, even though the rates of wear varied by several orders of magnitude between the different tests and even though there was a distinct change in wear mechanism from almost pure surface fatigue to almost pure cutting from one end of the spectrum to the other. (Edited author abstract) 11 refs.

Larsen-Basse, Jørn (Georgia Inst of Technology, Atlanta, GA, USA); Tadjvar, Ahmad. *Wear* v 122 n 2 Mar 1 1988 p 135-149.

**082409 RECENT STUDIES ON FRETTEING WEAR OF POLYMERIC MATERIALS.** A critical review of recent studies is presented from the standpoint of the fundamental aspects of fretting wear of polymeric materials. Experimental results concerning fretting damage of polycarbonate, polytetrafluoroethylene, polyethylene, polyvinylidene fluoride, polychlorotrifluoroethylene, polyvinylchloride, polymethyl methacrylate and polyhexamethylene adipamide are cited. The mechanism of fretting damage is discussed from the standpoint of the direct observations of the fretting of polymethyl methacrylate against steel with an optical microscope. These results indicate that the coefficient of friction, the melting or welding temperature, and the thermal conductivity are important factors in the fretting wear of polymeric materials. **082410 ELASTIC-PLASTIC STRESS ANALYSIS OF A POLYMERIC SUBSURFACE WITH A THIN LAYER UNDER NORMAL AND TANGENTIAL LOADING.** A finite element method was employed to investigate the stress and strain distributions in the subsurface of high density polyethylene (HDPE) by an elastic-plastic analysis. Various equivalent stress and strain contours in the subsurface area under the asperity contact were obtained for three kinds of HDPE, i.e., gamma-ray-irradiated HDPE, helium-plasma-treated HDPE, and untreated HDPE. It was assumed that the untreated HDPE has a soft surface layer over the bulk, the plasma-treated HDPE has a hard surface layer, and the gamma-irradiated HDPE has a homogeneous surface area owing to uniform crosslinking. The wear mechanisms of untreated and irradiated HDPE were explained qualitatively on the basis of the plastic deformation and strength of the material. (Edited author abstract) 39 refs.

**082411 PARAMETRIZATION OF THE FRICTION CONSTANT FOR STOCHASTIC SIMULATIONS OF POLYMERS.** A method is developed for determining the values of the friction constants for atoms in polymers for Langevin and Brownian dynamics simulations. The method is based on calculating effective hydrodynamic radii that take into account the reduction of the atomic surface area accessible to solvent. The resulting friction constants are shown to give satisfactory translational and rotational diffusion coefficients when compared with experimental data. Analysis of the effect of hydrodynamic interaction on translational and rotational dynamics shows that it is significantly smaller for the latter than the former. Limitations of point-source frictional models are briefly discussed. (Author abstract) 48 refs.

**082412 COEFFICIENT OF FRICTION OF A POLYAMIDE/POLYMETHYL METHACRYLATE BLEND SYSTEM.** The coefficient of friction is an important tribological property of polymer materials. In this work, values for the coefficient of friction of a polyamide (nylon 6,6)/polymethyl methacrylate (PMMA) blend system have been measured under various compressive stresses. The results show that the coefficient of friction of the amorphous polymer, PMMA, increases with increasing compressive stress; while the coefficient of friction of the crystalline polymer, nylon 6,6, either stays constant or decreases with increasing compressive stress. For crystalline polymers, the coefficient of friction measured parallel to the flow direction is lower than that measured perpendicular to the flow direction. The effect of sample orientation on the coefficient of friction of the amorphous polymer, PMMA, is insignificant. Values for the coefficient of friction of the blends measured are lower than those calculated from the additive rule for the coefficient of friction of the blend system. (Edited author abstract) 10 refs.

**082413 APPROACH TO THE COMPOSITION DEPENDENCE OF THE GLASS TRANSITION TEMPERATURE OF COMPATIBLE POLYMER BLENDS: 1.** Starting with the idea that, besides conformational energy barriers, surface contacts are responsible for both conformation and 'free' volume distribution, a new concept is developed to describe the glass transition in compatible polymer blends. An extended Gordon-Taylor equation results if both the effective contact probabilities of the blend components and the effect of molecular surroundings on the contact contribution to the glass transition of the blend are considered. Free volume redistribution due to surface contacts is included. The Gordon-Taylor constant K of the relation obtained is now not a fitting parameter, but is related to the ratio of the different expansion coefficients of the free volume. The relation introduces two fitting parameters, K<sub>1</sub> and K<sub>2</sub>, which are related to the intensity of polymer-polymer interaction and to the effect of immediate molecular surroundings on the interaction. Data analysis suggests that these fitting parameters are not only polymer-specific, but also molecular-weight-dependent. (Author abstract) 24 refs.

**082414 GRAFTING ONTO CARBON BLACK BY THE REACTION OF REACTIVE CARBON BLACK HAVING MASKED ISOCYANATE OR ACYL AZ-**

**IDE GROUP WITH FUNCTIONAL POLYMERS.** Although isocyanate group (NCO) introduced onto carbon black surface was inactivated rapidly upon storage, it could be stabilized by masking the NCO group with active hydrogen compounds such as acetylacetone, diethyl malonate, and sodium hydrogensulfite. Upon heating these carbon blacks having masked NCO group at 150°C, the NCO group was regenerated on carbon black by the decomposition of the masked NCO group. On the other hand, acyl azide (CON<sub>3</sub>) group introduced onto carbon black was stable at below 20°C, but readily decomposed to NCO group by heating. By means of the reaction of NCO group on carbon black with functional polymers having hydroxyl, amino, and carboxyl group, these polymers were effectively grafted onto carbon black surface. (Edited author abstract) 8 refs.

**082415 COLLAPSE OF GRAFTED CHAINS IN POOR SOLVENTS.** A mean field theory of the collapse of grafted chains (consisting of N monomers) in a poor solvent is presented. The collapse behavior of nonoverlapping grafted chains is identical to that of free coils but with no phase separation. This 'strong' collapse, in which the coil radius R decreases continuously from R approximately N<sup>3/5</sup> in a good solvent to R approximately N<sup>1/3</sup> in a poor solvent, is replaced by 'weak' collapse for densely grafted layers. Such a layer when undergoing 'weak' collapse becomes thinner, yet the chains remain stretched even in poor solvents, and the layer thickness is linear in N past the collapse. For low densities the 'weak' collapse is associated with a first order phase transition. An increase in grafting density takes the system through a critical point into a gradual collapse regime. (Author abstract) 16 refs.

**082416 GRAFTING OF VINYL ACETATE ONTO POLY(VINYL CHLORIDE) IN SOLUTION.** Radiation-induced grafting of vinyl acetate (VAc) onto poly(vinyl chloride) (PVC) was performed in solution with dimethylformamide (DMF). Grafting was studied as a function of dose, dose rate, and VAc/PVC ratio. The amount of grafting was measured by IR spectroscopy on the graft copolymer fraction insoluble in hot methanol. The homopolymerization of VAc was also studied in the same conditions, in order to check the influence of the solvent on radiochemical reactions leading to graft copolymers. The results show that the grafting can be easily obtained. The graft copolymer was tested for the preparation of ultrafiltration membranes. (Edited author abstract) 20 refs.

**082417 FACTORS AFFECTING PHOTOGRAFTING OF METHACRYLIC ACID ON POLYETHYLENE FILM IN LIQUID PHASE SYSTEM.** Factors affecting photografting of methacrylic acid on low-density polyethylene film were investigated in liquid-phase system with water. Benzophenone was used as a sensitizer by coating it on the film surface. Factors examined were monomer concentration, polymerization temperature and film thickness. It was found that grafted polymer is formed preferentially as compared with homopolymer under conditions such as monomer concentration higher than 6.0 wt%, polymerization temperature higher than 50°C, and film thickness of 30 µm. The structure of the grafted samples obtained in the above systems was characterized by the grafted chains distributing over the film and the flat appearance of film surface. (Edited author abstract) 13 refs.

## Heat Resisting

**082418 THERMAL STABILITY OF SOME POLYQUINAZOLONE POLYMERS: EFFECT OF ACID CATALYSIS.** Thermal properties of polyquinazolones (PQ) polymers prepared from 4,4'-diaminodiphenyl-3,3'-dicarboxylic acid (BDC) and 4, 6-diaminoisophthalic acid (DAIA) with diacetamido derivative of a number of diamines have been studied by thermogravimetry (TG) and differential scanning calorimetry (DSC). The effect of acid catalysis was also investigated. The results show that polyquinazolones prepared from DAIA have higher thermal stabilities and glass transition temperatures compared to those prepared from BDC. This can be attributed to the more stable and rigid fused quinazalone backbone unit in the PQ/DAIA system. Both polymer systems show improved thermal stability in the presence of catalyst which is a direct result of increased number of fully cyclized quinazalone rings in the polymer. (Author abstract) 6 refs.

**082419 BIS- OR TETRA-MALEIMIDES OF SUBSTITUTED s-TRIAZINES CHAIN-EXTENDED BY IMIDE, AMIDE, AND UREA GROUPS FOR FIRE- AND HEAT-RESISTANT APPLICATIONS.** Novel phosphorylated bismaleimides and nonphosphorylated tetramaleimides containing substituted s-triazine rings (chain-extended by imide, amide, or urea groups) were prepared and polymerized. These polymer precursors were prepared by reacting 2,4-bis(4-aminophenoxy)-6-diethoxyphosphinyl-s-triazine or 2,4,6-tris(4-aminophenoxy)-s-triazine with maleic anhydride in combination with a bridging agent such as pyromellitic or benzophenone tetracarboxylic dianhydride, terephthaloyl chloride, and tolylene diisocyanate. The structure of polymer precursors was confirmed by infrared and proton nuclear magnetic resonance spectroscopy and their curing behavior was investigated by differential thermal analysis. The phosphorylated bismaleimides were thermally polymerized at a lower temperature than did the corresponding nonphosphorylated tetramaleimides. Dynamic thermogravimetric analysis showed that the nonphosphorylated and phosphorylated cured resins were stable up to 320-370 and 312-327°C, respectively, in nitrogen or air atmosphere. (Edited author abstract) 17 refs.

**082420 HIGH-PERFORMANCE POLYMERS.** A process description given of a range of aromatic polymers manufactured by condensation polymerization in an aprotic aromatic solvent. The monomers themselves may be formed in the reaction stage or prepared and isolated as a separate stage. A key aspect of the process is easy molecular weight control. This permits us to manufacture materials having good processability and mechanical properties. In the process, molecular weight is controlled primarily by varying the mole ratios of halogen ends on the monomers to the hydroxyl or -OM ends. This control of molecular weight by varying the stoichiometry has allowed easy tailoring of the molecular weight to meet commercial requirements. Also discussed is the production of the ketone family of polymers. This commercial polymerization process for world-scale manufacture of aromatic polymers has proved itself robust and versatile, allowing the exploitation of a wide range of polymer types. This technology has been extended to amorphous and crystalline polymers suited for markets that require easier processability, higher temperature performance, and specialist applications.

## High Temperature Applications

**082424 ADDITION POLYMERS FROM 1,4,5,8-TETRAHYDRO-1,4,5,8-DIEPOXYANTHRACENE AND BIS-DIENES: PROCESSABLE RESINS FOR HIGH TEMPERATURE APPLICATIONS.** 1,4,5,8-Tetrahydro-1,4,5,8-diepoxyanthracene reacts with various anthracene end-capped polyimide oligomers to form Diels-Alder cycloaddition copolymers. The polymers are soluble in common organic solvents, and have molecular weights of approximately 21,000 to 32,000. These resins appear to be more stable in air than in nitrogen; this is shown to be due to a unique dehydration (loss of water ranges from 2 to 5 percent) at temperatures of 390 to 400°C to give thermo-oxidatively stable pentiptycene units along the polymer backbone. Because of their high softening points and good thermo-oxidative stability, the polymers have potential as processable, matrix resins for high-temperature composite applications. ## Ignition

**082428 INITIATION OF COMBUSTION FOR CHLORINATED POLYETHYLENES.** The existence of a different mechanism for self-ignition of solids and gases is due to the more limited role of reaction temperature for the medium as a result of the diffusion nature of combustion for a solid. The specific nature of warmup during ignition of solid materials has induced authors to modify the system of evaluating their combustibility. In order to determine the self-ignition temperature a modified method and equipment for carrying it out is suggested. The incombustibility of highly chlorinated polymers makes them candidate materials for fire proofing. 13 refs.

**082432 Co-INJECTION CHARTING NEW TERRITORY AND OPENING NEW MARKETS.** The process was developed more than 15 years ago by ICI in the UK. Battenfeld, in those days Schloemann-Siemag incorporated the process with machine technology in the early 1970s. The process has been commercially used since 1975. Two materials, one for skin and one for core, are injected in such a way that one material forms the skin and the other forms the core. To make sure that an even distribution of skin and core can be achieved without any visible marks on the surface, Battenfeld developed the two-channel technique. With the two-channel nozzle, parts can be produced with surface qualities which are as good as straight injection molded parts.

**082435 PRESSURE TRANSFER DURING THE INJECTION MOLDING PROCESS ACCORDING TO IMPROVED CHANGE-OVER TO HOLDING PRESSURE.** When changing over from the injection process to the follow-up pressure phase, pressure peaks can result in flashing of the mold. Perfect closed-loop control is rendered difficult, because the pressure profile in the injection cylinder is usually not proportional to the pressure profile in the screw ante-chamber. Results of pressure measurements taken in the injection cylinder, the screw ante-chamber and a spiral flow mold of a machine equipped with a newly developed follow-up pressure change-over system are illustrated and discussed. (Edited author abstract) 3 refs.

Ries, H.; Stillhard, B. *Kunstst Ger Plast* v 77 n 12 Dec 1987 p 15-18.

## Ion Implantation

**082436 CONDUCTING POLYMERS BY ION IMPLANTATION.** An electrically conductive surface can be created by using the ion implantation process on nonconducting polymeric sheet. The resulting conductivity was measured and correlated to ion beam parameters, such as ion species, dose, and energy. Additionally, a reaction model, in both physical and chemical terms, was proposed, which can assist in understanding of the underlying mechanisms during the ion implantation of polymers. The surface microscopic structure of the ion-implanted polymer specimens was evaluated by x-ray photoelectron spectroscopy (XPS), electron spin resonance (ESR), Rutherford backscattering spectroscopy (RBS), and infrared spectroscopy (IR). The experimental results indicated that the ion bombardment process leads to a carbon-enriched material in a manner akin to the carbonization of organic films observed upon pyrolytic processing. (Author abstract) 14 refs.

**082438 ALKALI METAL ION-POLY(ETHYLENE OXIDE) COMPLEXES. II. EFFECT OF CATION ON CONDUCTIVITY.** In order to aid understanding of the mechanism of ionic conductivity the authors have examined systematically complexes of poly(ethylene oxide) (PEO) with the alkali metal salt series of  $\text{Li}^+$ ,  $\text{Na}^+$ ,  $\text{K}^+$ ,  $\text{Rb}^+$  and  $\text{Cs}^+$  with both tetrafluoroborate ( $\text{BF}_4^-$ ) and trifluoromethanesulfonate ( $\text{CF}_3\text{SO}_3^-$ ) anions. The ratio of monomer to salt was 10:1 in all cases. Complex impedance measurements were made on all samples in the temperature range 40°-125°C. with  $\text{CF}_3\text{SO}_3^-$  as the anion a definite trend was apparent with the smallest cation  $\text{Li}^+$  being the worst conductor and  $\text{Cs}^+$ , the largest cation, being the best. When  $\text{BF}_4^-$  salts are used, the  $\text{Na}^+$  complex is found to be the best conductor and  $\text{Rb}^+$  the worst. This study, in connection with earlier studies, has shown that synergy between cation and anion in the polymer matrix is an important consideration in determining the ionic conductivity. (Edited author abstract) 12 refs.

## Isomerization

**082439 NEW ISOMERS OF POLY(VINYL FLUORIDE) WITH CONTROLLED REGIOSEQUENCE MICROSTRUCTURE.** A novel synthetic procedure is described to adjust regiosequence defects (caused by monomer reversals during chain propagation) by reductive dechlorination of precursor copolymers of vinyl fluoride, VF, with suitable chlorofluoroethylenes, using tributyltin hydride to replace chlorine quantitatively with hydrogen. The products are regioisomers of PVF with defect levels depending on the identity of the chlorofluoroethylene monomer, and the composition of the precursor copolymer, which is selected by adjusting the comonomer feed ratio. We measure the regiosequence distribution of these various PVF isomers by 470 MHz  $^{19}\text{F}$  nuclear magnetic resonance, and show that the polymers are stereoirregular (atactic) as well. The crystalline melting temperature of PVF increases as the polymer becomes more isoregic. 10 refs.

**082442 HETEROCOAGULATION OF POLYMER LATTICES WITH SPHERICAL SILICA; ADSORPTION OF LATEX PARTICLES ONTO SILICA PARTICLE SURFACE AND ITS DESORPTION BEHAVIOR.** The adsorption behavior of amphoteric polymer lattices with a radius of 125 nm on large spherical particles of silica was studied as a function of pH, electrolyte concentration and the particle number concentration. Under the usual conditions, the adsorption isotherms are of a high affinity type with a pronounced plateau; the plateau value increases with increasing the electrolyte concentrations. Desorption experiments show that the adsorption is essentially irreversible except for the adsorption which occurred under high alkaline conditions (pH > 11.5). **082443 STUDY ON LATEX STABILITY AND PERMEATION OF COAGULANT IONS ON SEED COAGULATION OF POLYMER LATEX.** The decrease of latex stability during the step of growing particles in the seed coagulation of polymer latex was studied and the following results were obtained. The decrease of the stability is caused by the permeation of coagulant ions from particles into latex dispersion medium. The rate of the ion permeation is proportional to the rate of growing particles. The rate of the ion permeation increased with temperature corresponds to the increase of diffusion coefficient of the ion. (Author abstract) In Japanese. 4 refs.

**082444 APPLICATION OF INTERACTIVE IMAGE ANALYSIS TO LIGHT SCATTERING PATTERNS OF SOME POLYMER SYSTEMS.** In this paper we describe a system for interactive picture analysis useful for extraction of various types of physical information from both real- and Fourier-space images. The possibility of hardware and software operations are illustrated, with examples of applications such as analysis of light scattering patterns from phase separated systems, semicrystalline polymer films with significant supermolecular morphology and from less regular polymer systems with a pronounced 'speckle effect'. The analysis concentrates on both spatial and time dependent scattering processes and measurements of intensity correlation of scattered light. Although the present examples of application are limited to light scattering patterns of polymer systems, the technique of interactive picture analysis is useful for quantitative extraction of information from real- and Fourier-space images of arbitrary structure. **082445 ELONGATIONAL FLOW BIREFRINGENCE OF POLY(STYRENE SULFONATE).** The elongational flow birefringence of aqueous poly(styrene sodium sulfonate) solutions has been measured in a crossed-slot flow cell. The relaxation times calculated

from the onset of birefringence were significantly longer than relaxation times determined from intrinsic viscosity measurements or reported for transient electric birefringence measurements. Direct observation of the flow birefringence patterns showed a more complex pattern than expected for simple non-interacting flexible polymers. A molecular connectedness of the flow-elongated polymers, was the most plausible explanation for the longer relaxation times, even for polymer concentrations well below the overlap concentration. (Author abstract) 15 refs.

**082446 POLYMERS AT LOW TEMPERATURES.** This conference proceedings contains 13 papers. Low temperature properties and applications of polymers are covered. Some of the properties discussed are mechanical properties, chemical resistance, dielectric properties, physical properties, microstructure, glass transition, fracture, and thermal effects. The low temperature applications include rubber products, plastic foams as insulation for liquefied natural gas tanks; polymer tapes for superconducting cables; and elastomeric seals. Technical and professional papers from this conference are indexed and abstracted with the conference code no. 11284 in the Ei Engineering Meetings (TM) database produced by Engineering Information, Inc.

**Lubrication**

**082447 LUBRICATION OF MINIATURE POLYMERIC SYSTEMS - A REVIEW.** The lubrication of miniature polymeric systems, i.e., metal-polymer or polymer-polymer material combinations is a very effective way to improve their tribological properties, and especially to reduce their wear as compared to the wear during unlubricated sliding. The oil should effectively wet the polymers used, have a different solubility parameter and consist of a high-molecular-weight substance (e.g., fluorinated polyether having a molecular weight ranging from 5000 to 10,000). To achieve a large reduction in adhesion by introducing oil between the rubbing surfaces, and to minimize spreading, the surface tension of the oil should be as high as possible. For the lubrication of metal-polymer systems it is reasonable to use oil having a dielectric constant higher than that of the polymer, and in the case of a polymer-polymer or any other dielectric-polymer contact, the dielectric constant of the oil should be kept between the dielectric constants of the materials used. 39 refs.

**Magnetic Field Effects**

**082448 STATISTICS OF POLYMER CHAINS IN ORIENTING FIELDS.** The theory of a freely jointed polymer chain is modified by introduction of interactions between dipole chain segments and an orienting field. Such a field results either from external forces (e. g. external electric or magnetic fields) or represents interactions between dipole segments of chains (molecular mean-field). The distribution of orientations of chain segments and the free energy of a chain in such orienting fields are calculated and discussed. (Author abstract). 13 Refs.

**082449 FERROMAGNETISM IN A NEW TYPE OF ORGANIC POLYMER BASED ON BENZENE RINGS BRIDGED BY CARBONS.** A new organic polymer with a three-dimensional network of carbons is proposed as a prototype organic ferromagnet. It is composed of benzene rings bridged by carbon atoms. The ground and the excited states of  $\pi$  electrons of this polymer are studied within the Hubbard model combined with the mean-field theory, and it turns out that this polymer becomes a ferromagnet (a ferrimagnet). The one-electron energy band and the spin density at each carbon atom as well as the magnon spectrum are calculated. (Author abstract) 16 refs.

**082450 CORROSION RESISTANCE OF STRUCTURAL MATERIALS IN MEDIA FOR PRODUCTION OF POLYVINYL BUTYRAL FOR OPTICAL APPLICATIONS.** Investigations were conducted into the corrosion of working equipment for production of PVB, (adhesive and varnish grades). In addition to this, specimens of various steel and alloys with coatings and without coatings were tested in the industrial conditions of production of PVB and in experimental equipment for production of PVB. Examination of equipment and the results of the corrosive tests show that the carbon steels cannot be used for the manufacture of equipment used in the production of PVB, since it is necessary to ensure the cleanliness of the final production with respect to their iron ion content; 12Kh18N10T corrosion-resisting steel used for the manufacture of certain members of equipment used in various stages of polymerization, saponification, dissolution of PVS, and preliminary drying of PVS is not recommended for this application. For equipment where various protective coatings cannot be used, or the use of these coatings is inefficient because of the service conditions, it is recommended that corrosion-resisting nickel-containing steels, clad steels, KhN65MV alloy, and titanium be used. 3 refs.

**082452 NEW ORGANOMETALLIC POLYMERS CONTAINING TUNGSTEN CARBENE COMPLEXES.** The authors report on the polymerization of the tungsten-carbene vinyl monomer 1, which affords the first polymeric material 2 to contain repeating transition-metal carbene fragments, the characterization of this new polymer, and some initial findings dealing with its reactivity. It is shown that upon preparing the  $\alpha,\beta$ -unsaturated tungsten carbene complex 1, an insoluble orange solid was frequently observed. Nevertheless, this orange solid could be avoided if complex 1 was purified immediately after preparation and then stored at  $-30^\circ\text{C}$ . Purification involved chromatography on silica gel at  $-20^\circ\text{C}$  with the resulting pentane eluent collected at  $0^\circ\text{C}$ . It was subse-

quently found that if complex 1 was allowed to melt (ca. 10°C) and then stand at this temperature in a nitrogen atmosphere for 7 days, a dark red polymeric glass formed. 31 refs.

## Mathematical Models

**082453 MECHANICAL INSTABILITY OF AMORPHOUS POLYMERIC NETWORKS: ASYMMETRIC DEFORMATION UNDER SYMMETRIC BIAxIAL TENSION.** Asymmetric deformation of a symmetrically loaded rubber sheet was observed, many years ago, by L.R.G. Treloar in his experiments on natural rubber. The problem has recently been studied by E.A. Kearsley, and the possibility of asymmetric deformations in an equi-biaxial state of force is predicted by the use of phenomenological constitutive relations. In the present study, the problem is analyzed in relation to the molecular constitution of rubber networks. It is shown that mechanical instability in symmetrically loaded networks may be possible only for limited choices of molecular parameters such as junction functionality, degree of crosslinking, and the degree of swelling during crosslinking and during deformation. Stability of multiple valued deformations is discussed by thermodynamic considerations of the elastic potential. (Edited author abstract) 12 refs.

**082456 MONTE CARLO SIMULATION OF LATTICE MODELS FOR MACROMOLECULES.** This article reviews various methods for the Monte Carlo simulation of models for long flexible polymer chains; namely self-avoiding random walks at various lattices. This problem belongs to the classical applications of Monte Carlo methods since more than thirty years, and numerous techniques have been devised. Nevertheless, there are still many open questions, relating to the validity of the algorithms in principle, as well as to the accuracy of the results that can be obtained in practice. This review presents a brief introduction to these problems, discusses the basic ideas on which the various algorithms are based as well as their limitations, and describes a few typical physical applications. Most emphasis is on the simulation of single, isolated chains representing macromolecules in dilute solution, but the simulation of many-chain systems is also dealt with briefly. An outlook on related problems (simulation of off-lattice chains, branched instead of linear

polymers, etc.) is also given, as well as a discussion of prospects for future work. (Author abstract). 222 Refs.

**082457 EFFECTS OF FREE VOLUME ON STRESS RELAXATION WITH BOND BREAKING IN POLYMERIC MATERIALS.** This work is a part of a program aimed at understanding the response of polymer chains to external mechanical forces. The response may be nondestructive or destructive, and competition between the two types exists. Molecular dynamics was used to simulate systems of polymer chains on a computer. A constant strain was imposed, as in experimental stress relaxation tests. Free volume was varied, and its effect on relaxation rate and on bond breaking was studied. A crossover exists between the region in which the chain relaxation capability is sufficient and the region where the breaking of a small number of bonds leads to crack propagation. The results are significant for polymers, conventional polymer-based composites, and liquid-crystalline molecular composites. (Author abstract) 24 refs.

**082458 EXPERIMENTAL AND THEORETICAL STUDIES ON THE REDOX PROPERTIES OF CONDUCTING POLYMERS.** Voltammetric measurements on selected polypyrrole (PPy) films and defined soluble oligomers belonging to the oligo-p-phenylene and the oligo-p-phenylenevinylene series provide new insights into the charging/discharging properties of conducting polymers. It turns out that the current response in the whole accessible potential range of conventional conducting polymers is mainly caused by faradaic charge transfer reactions rather than capacitive effects. This is supported by digital simulations which are based on a model of n-fold electron transfers within a finite layer. In addition, from the data of defined oligomers it becomes clear that the number and energies of accessible redox states in such materials depend on the extension of conjugation in the monomeric unit and on the chain length of the polymer. **082459 DETERMINATION OF THE FLEXIBILITY PARAMETER OF POLYMERS.** This paper deals with the determination, in theta conditions, of the flexibility parameter  $\lambda$  defined by Kratky-Porod for random-coiled polymers, using three different methods: (a) from hydrodynamic data in  $\theta$  conditions, (b) by using a new form of extrapolation to zero of the corresponding values for the average molecular weight, and (c) by extrapolation of  $\lambda$  tending to zero. From method (b), values of the interaction parameter, B, were in agreement with those from Stockmayer-Fixman theory. (Edited author abstract) 48 refs.

**082461 MOLECULAR WEIGHT DEPENDENCE OF MECHANICAL PROPERTIES OF POLY(p,p'-OXYDIPHENYLENE PYROMELLITIMIDE) FILMS.** The mechanical properties, i.e., Young's modulus, elongation, and tensile stress, were determined as functions of the molecular weight for films of poly(oxydi-p-phenylene pyromellitimide) prepared by thermal cyclization of the precursor poly(amic acid). The molecular weights of the samples were controlled by the monomer stoichiometry employed for the solution condensation of pyromellitic dianhydride and p,p'-oxydianiline. Weight-average molecular weights were determined by light scattering of the precursor poly(amic acid) as well as the fully cyclized polyimide. (Edited author abstract) 14 refs.

**082463 METHODS OF INVESTIGATION: THE TECHNIQUE FOR THE DETERMINATION OF THE DISCONTINUOUS LEVELS OF STRENGTH ON POLYMERS.** The aim of this paper is to show on the basis of a more statistically significant range of samples that the reproducibility of the discrete levels of strength is real. It is to be verified at the same time that the nature of the results is connected with the structure of the polymer films and that the results are not dependent on random variation in processing of experimental results. The reproducibility of the distribution curves for the strength of PET films obtained by statistical methods during repeated testing has been analyzed. With a sufficient number of samples, seven distinct levels of strength were reproducibly detected. (Edited author abstract) 6 refs.

**082464 STRUCTURE AND PROPERTIES OF FATIGUED SEGMENTED POLY(URETHANEUREA)S II. STRUCTURAL ANALYSES OF FATIGUE MECHANISM.** The fatigue mechanism of segmented poly(urethaneurea)s due to a sinusoidal strain was investigated from the structural point of view by means of small angle light scattering (SALS), small angle X-ray scattering (SAXS), and infrared dichroism (IRD) and was compared with the uniaxial deformation mechanism. The SALS

patterns of the original sample films indicated the existence of a spherulite texture. There appeared a ring diffraction pattern in the SAXS photograph for the as-cast sample. The fatigued mechanism is proposed in order to account for the experimental results based on the spherulite deformation model. It was also found that samples having longer soft segments have higher degree of phase separation at the beginning and that these mechanical properties and orientational behavior are less sensitive to fatigue time. (Edited author abstract) 25 refs.

**082465 EFFECT OF METHYLENE CHLORIDE SORPTION ON THE MECHANICAL PROPERTIES OF POLY(ARYL-ETHER-ETHER-KETONE) (PEEK).** The effect of sorbed methylene chloride on the tensile strength and fatigue crack growth (FCG) resistance of PEEK were determined. PEEK sorbs up to 23 wt% methylene chloride; the transport process is essentially Case II, that is, the methylene chloride advances as a sharp front. Sorbed methylene chloride significantly reduces the tensile strength of neat PEEK and the strength reduction is linearly proportional to the amount of solvent sorbed. FCG rates in neat PEEK are increased by the methylene chloride sorption. At saturation, the FCG rates are two orders of magnitude higher than in dry PEEK. Methylene chloride plasticizes the resin, thereby reducing its glass transition temperature ( $T_g$ ), tensile strength, and FCG resistance. (Author abstract) 4 refs.

**082467 EFFECTS OF MECHANICAL DRAWING ON THE STRUCTURE AND PROPERTIES OF PEEK.** This study examines the effects of crystallinity and temperature on the mechanical properties of PEEK. Crystallinity in PEEK increases with annealing temperature up to a maximum of 28 percent with a melting point at 335°C. A minor melting peak also occurs about 10°C above the annealing temperature. In cold drawing the samples exhibited a yield stress and necking followed by homogeneous drawing. The yield stress increases with crystallinity, but there is no change in the modulus. The extension in the necking process also increases with crystallinity, however there is only a slight increase in extension-to-break since necking is compensated by the final amount of homogeneous drawing. The yield stress of PEEK when drawn at  $T_g(145^\circ\text{C})$  is significantly lower than at room temperature indicating a reduction in mechanical properties at temperatures approaching  $T_g$ . After mechanical drawing the minor melting peak disappears and on heating the material undergoes cold crystallization near the onset of  $T_g$ . (Edited author abstract) 16 refs.

**082470 TOUGHENED BLENDS OF POLY(BUTYLENE TEREPHTHALATE) AND BPA POLYCARBONATE. PART 2: TOUGHENING MECHANISMS.** The toughening mechanisms of blends of poly(butylene terephthalate) (PBT) and bisphenol-A polycarbonate (PC) toughened with core/shell impact modifier have been studied by transmission electron microscopy, notched impact testing and uniaxial tensile dilatometry. In toughened PBT and toughened PBT/PC blends, shear deformation is the major toughened mechanism. Brittleness at low temperatures is caused by a reduction in the major toughening mechanism. Brittleness at low temperatures is caused by a reduction in the ability of the matrix to undergo shear deformation. In tensile dilatometry this effect is indicated by an increase in the internal cavitation of the impact modifier particles. The low temperature impact toughness of toughened PBT/PC blends is greater than that of toughened PBT. Modification of PBT with partially miscible PC appears to have a beneficial effect on the ability to undergo shear deformation. This effect has been attributed to the PC residing in the amorphous interlamellar regions of the PBT spherulites, thus facilitating interlamellar slip. (Author abstract) 8 refs.

**082471 METHODS OF INVESTIGATION USE OF THE TEMPERATURE WAVE METHOD FOR INVESTIGATING THERMAL RELAXATIONAL PROCESSES IN POLYMERS.** The method of temperature waves is used for the first time to determine the complex thermophysical characteristics of materials, and the advantages of the method are considered. In the case of flat temperature waves, the solution of the linear problems of heat conductivity, making due allowance for the finite character of the rate of heat dissipation, provides a means of deriving expression for calculating the moduli and arguments of complex thermophysical characteristics. In the region of the glass transition temperature of polyvinyl acetate (PVA) its thermophysical characteristics are complex quantities depending on the frequency of the temperature vibrations, which reflects the relaxational character of the heat accumulation and transfer processes associated with segmental mobility. (Author abstract) 11 refs.

**082472 METHOD FOR CALCULATING DYNAMIC MECHANICAL PROPERTIES USING FOURIER TRANSFORMS OF PULSE DEFORMATION EXPERIMENTS.** A general method for determining the dynamic mechanical properties of a material is presented. It involves Fourier transforms of the stress and strain responses of a material subject to arbitrary deformation. As an example, uniaxial pulse-strain deformations were used to calculate the dynamic properties of a cured

epoxy. A comparison of the properties calculated from uniaxial sinusoidal deformations and those obtained by Fourier transform analysis of the uniaxial pulse-strain indicate excellent agreement over a wide range in mechanical behavior. These results suggest that dynamic mechanical properties may be obtained when deformations other than that of a sine wave are used. (Author abstract) 4 refs.

**082473 EXPERIMENTAL VERIFICATION OF A MICROBUCKLING MODEL FOR THE AXIAL COMPRESSIVE FAILURE OF HIGH PERFORMANCE POLYMER FIBRES.** A previously derived theoretical compressive strength for fibres composed of uniaxially oriented and extended polymer chains is compared with the measured strengths of several high performance fibres. For failure initiated by elastic microbuckling of polymer chains or fibrils, the maximum fibre strength is predicted to be equal to the minimum longitudinal shear modulus of the fibre. An excellent linear correlation between measured strengths and torsion moduli was obtained for four liquid crystalline polymer fibres and high modulus graphite fibres. The correlation shows that measured strengths are 30% of the corresponding torsion moduli for these fibres. A high modulus, high strength polyethylene fibre exhibited a compressive strength-torsion modulus ratio that was lower than the value 0.3 obtained for the other fibres examined. (Author abstract) 39 refs.

**082474 MAKING THE PLASTICS CONNECTION.** Improvements in the performance of engineering plastics has made them ideal materials for use in the electronics industry, and particularly for use as connectors. Good dimensional stability, high electrical insulation properties, and improved thermal properties have all combined to expand the opportunities available to the plastics suppliers in the electronics industry. With liquid crystal polymers (LCPs), the effect is to produce an anisotropic structure which is stronger and stiffer than other types of plastic. Significant properties of this material include the ability to tune the thermal expansion to zero, positive, or even negative values, and so match virtually any substrate. The material also has a very high temperature tolerance. Vectra is the best known of the LCPs, and a case-study of the selection of Vectra for a parallel interconnect indicates some of the key properties of this material.

Anon. *Eng Mater Des* v 32 n 6 Jun 1988 p 25-26, 28-29.

**082475 NEW METHOD FOR WORKING OUT  $\alpha_T$  (T) FROM DYNAMIC MECHANICAL TEMPERATURE SPECTRA.** A method is developed for determining  $\alpha_T(T)$  from dynamic mechanical temperature spectrum. This method provides a new and simple means for obtaining  $\alpha_T(T)$  of polymers. It is shown that viscoelastic properties predicted by calculation are in agreement with the experimental results. The combination of previous and present papers has established the theory and method for determining relaxation and retardation spectra and other viscoelastic functions from dynamic mechanical temperature spectrum at a constant frequency. The results for polyethylene terephthalate fibers are presented. 3 refs.

**082476 TYPES AND MECHANISMS OF NON-LINEARITY IN THE MECHANICAL BEHAVIOUR OF POLYMERS.** The concepts of possible types of non-linear mechanical behavior of polymeric materials and of different mechanisms responsible for the non-linearity are generalized. The weak (geometrical) non-linearity depends on an intrinsic material function

(relaxation spectrum) which characterizes the linear behavior of the material. The strong (physical) non-linearity is associated with reorganization of structure, although in some instances it is also governed by the linear relaxation spectrum. The ultimate non-linearity, reflected in a stepwise change of properties, appearance of instabilities, and a loss of material integrity, is given by phase or relaxation transitions induced by deformation. (Edited author abstract). 19 Refs.

**082479 PREDICTION OF DRUG SOLUBILITIES IN POLYMERS.** We have recently discussed the correlation of octanol-water and polymer-water partition coefficients and the use of such correlations as a tool to estimate solubilities in polymers. The correlation permits determination of the relative solubilities of a solute in different polymers as a function of solute lipophilicity; when combined with the aqueous solubility of the solute, it may be used to estimate absolute solubilities in polymers. This ability to estimate relative and absolute solubilities is useful in such technologies as membrane separations, drug delivery, and polymer packaging. In this letter, we report more complete correlation data, analysis of which shows that the slope of the correlation equation for six polymers is proportional to the solubility parameter of the polymer, while the intercept can be derived from the solubility of water in the polymer bulk. 19 refs.

**082480 BIOMEDICAL APPLICATIONS OF SYNTHETIC POLYMERS.** Synthetic polymers are fast replacing conventional engineering materials in many fields. And the field of medicine is no exception. This article is an attempt to review the current status and the future prospects. A survey of the various medically useful polymers shows that no homopolymer can ever functionally mimic a given biological material. As a rule, all biological materials are composites with unique hierarchical organizations. It is solely because of this architectural style that they exhibit a combination of diverse engineering characteristics. Consequently the right way to design a synthetic substitute for a given biological tissue is to gain a thorough comprehension of the structural organization of the tissue at the molecular level. The next step is to try to reproduce that hierarchical organization with the medically selective materials. Attempts to produce carbon fiber reinforced composites of UHMWPE and HDPE are steps towards this goal. 58 refs.

**082481 SURFACE MODIFICATION BY A TWO-LIQUID PROCESS DEPOSITION OF A-B BLOCK COPOLYMERS.** The surface modification technique presented here involves the deposition of an A-B block copolymer onto the surface of a hydrophobic polymer. By employing a two-liquid method, the block copolymers are deposited onto the hydrophobic surface in such a way that the hydrophobic block is embedded into the solid while the hydrophilic block remains exposed at the surface. The deposition of the block copolymer increases the polar component of the solid's surface free energy and decreases the dispersion component. By depositing a block copolymer containing either polyethylene-oxide or polyvinylpyrrolidone as the hydrophilic block, the biocompatibility of that surface could be enhanced through the reduction of the solid-liquid interfacial free energy, and through the inhibition of protein adsorption by the steric repulsion by the polymeric chains. 18 refs.

**082482 HYDROGELS AS CONTACT LENS MATERIALS.** The contact lens does have certain unique features which set it apart from other areas of biomedicine. The design and fitting of the lens can play an overriding part in governing the patient's response to a given material, although this is to a large extent offset by the relative ease of insertion and removal of the device, which means that the clinician can optimize the 'fit' of the lens. Thus, it is much easier in this than most other fields to compare the response of reasonably large numbers of patients to different materials under conditions in which variables related to design and fitting have been isolated. For this reason, the research carried out in recent years into the use of polymers in contact lenses has provided information on a range of materials which will greatly assist future work on their use in other biomedical applications. 170 refs.

**082485 POLYMER MELT DYNAMICS MODEL WITH A RELAXATION TIME EXPONENT OF 10/3.** In this paper we present a more precise calculation for the time it takes a group of chains to empty a sphere for the

first time. In view of the Scher-Shlesinger hypothesis, this is related to the rate of junction loss and, hence, stress relaxation in the terminal zone. Within de Gennes's original reptation model of kink-generated motion, we follow Scher-Shlesinger to treat the measured polymer melt diffusion constant as a single chain quantity and the reptation time as a multichain quantity to reconcile for the first time the experimentally observed and theoretical compatible results  $D \approx M^{-2}$  and  $\tau_r \approx M^{10/3} / (\ln M)^{2/3}$  in which the logarithmic term would not ordinarily be detectable. 17 refs.

**082486 ERRORS IN OMITTING RADIAL CONVECTION IN POLYMER MELT FLOW SIMULATIONS.** In the past the numerical simulation of polymer melt flows in channels has usually been carried out by neglecting the radial velocity component in both the momentum and energy equations. Attempts to include it showed temperature oscillations becoming more severe for convection-dominated flows. New results based on a finite-element streamline-upwind/Petrov-Galerkin method to treat the convective and viscous dissipation terms show that in nonisothermal studies of polymer melt flows, the temperature gradients due to the temperature dependence of the shear viscosity create radial velocity components that cannot be ignored even in cases of straight channels. The errors in omitting radial convection from the calculations are examined by comparison with available results in the literature based on such simplifications for the wire-coating process. (Author abstract) 29 refs.

**082488 ON THE STRUCTURE OF GLASSY POLYMERS. VIII. USE OF Z CONTRAST TO ELUCIDATE THE MICROSTRUCTURE OF EPOXY AND POLYIMID RESINS.** The technique of ultramicrotomy of polymers, followed by staining of the resulting thin sections with heavy metal ions and viewing with Z enhancement in the scanning transmission electron microscope is described. When applied to anhydride-cured epoxy resins, the structure is found to be heterogeneously crosslinked on a scale of a few hundred angstrom. When the technique is applied to amine-cured epoxy resins, the microstructure is found to change from homogeneous to inhomogeneously crosslinked, depending on stoichiometries and cure cycles. For amine-cured resins whose cure conditions are within the range of microstructural change, the bright field of the stained specimens alone does not detect heterogeneities, and the Z contrast becomes crucial to discern the kind of microstructure. A commercial

polyimide film examined in the same way is found to exhibit systematic variations in structure through the thickness of the film. (Author abstract) 18 refs.

**082490 MICROFIBRILLAR NETWORK OF A RIGID ROD POLYMER. 1. VISUALIZATION BY ELECTRON MICROSCOPY.** In the coagulation stage of the spinning process of fibers and films from solutions of a rigid polymer, poly[p-phenylene(benzo[1,2-d,4,5-d'] (PBT), a monodomain nematic solution undergoes a transition to the solid state by the action of a nonsolvent. The morphology of coagulated PBT fibers and films is studied by electron microscopy, after impregnation with an epoxy resin. The basic structure formed during coagulation is observed to be an interconnected network of oriented microfibrils, having a typical width of about 100 Angstrom. Visualization of regions which have buckled under compression suggests the relevance of the buckling of the individual microfibrils to the ultimate compressive properties of PBT fibers and films. (Author abstract) 13 refs.

**082491 INFLUENCE OF MICROSTRUCTURE ON ELASTIC AND VISCOELASTIC PROPERTIES OF POLYETHER ETHER KETONE.** Dynamic, creep and static tests were conducted to characterize experimentally the linear elastic and viscoelastic properties of polyether ether ketone (PEEK) as a function of the degree of crystallinity. The semicrystalline polymer was modeled as a two-phase composite material. Values for crystalline modulus and effective crystallite aspect ratios have been extracted from the model. These values together with experimental creep compliance values for amorphous PEEK have been used to predict the creep response for intermediate levels of crystallinity, which compare well with the experimental data. Time-temperature shifting parameters obtained from dynamic mechanical studies compare well with those from creep experiments. At temperatures below 140°C, the shifting parameters were found to be approximately equal for all levels of crystallinity. Prediction for long-term creep has been made from these tests by properly accounting for physical aging phenomenon. (Author abstract) 23 refs.

#### Microstructures

**082495 FLUORESCENCE PROBE INVESTIGATION OF ANIONIC POLYMER-CATIONIC SURFACTANT INTERACTIONS.** Pyrene and pyrene-labeled poly(acrylic acid) were used as fluorescence probes to investigate the interactions between poly(acrylic acid) and dodecyltrimethylammonium bromide. The polarity dependence of the vibrational structure of the pyrene emission spectrum indicated the formation of micelle-like surfactant aggregates at concentrations that are significantly below the critical micelle concentration (cmc). The extent of excimer formation of the polymeric probe was found to depend significantly upon the surfactant concentration. These results were interpreted in terms of polymer conformational changes induced by surfactant as well as the static versus dynamic nature of excimer formation. (Author abstract) 10 refs.

**082496 DIFFUSION OF MISCIBLE POLYMERS IN MULTILAYER FILMS.** Thermal and optical properties of multilayer films of miscible polyethyloxazoline (PEOx) and poly(styrene-co-acrylonitrile) have been studied as a function of time and temperature. Differential scanning calorimetry showed that the distinct, characteristic T<sub>g</sub>'s of the component polymers of the original films disappear after only short heating periods above T<sub>g</sub>, and a single transition appears. The new transition region is

broad at first, but narrows on subsequent heating. The measurement of light transmittance as a function of wavelength through the heat-treated films also confirms the diffusion of the miscible polymers and gives results which are comparable to the thermal measurements. Films from immiscible polymers of polystyrene and PEOx retain their properties after various heat treatments. A qualitative discussion of the diffusion process as examined by the thermal measurements is presented. (Author abstract) 33 refs.

**082497 ELECTRON BEAM CHARACTERISTICS OF POLY(METHYL METHACRYLATE)-POLY(VINYL CHLORIDE) MIXTURES.** This communication describes the electron beam characteristics of mixtures of PVC and poly(methyl methacrylate). The poly(vinyl chloride) changes the character of the films from being degradative to crosslinking and indicates that it is not possible to achieve successful lithography using this approach to resist formulation. (Author abstract) 8 refs.

Hayward, David (Univ of Strathclyde, Glasgow, Scotl); Affrossman, Stanley; Petrick, Richard A. *Polym Commun (Guildford Engl)* v 28 n 12 Dec 1987 p 344-345.

**082498 INFLUENCE OF CHLORINATION OF POLY(VINYL CHLORIDE) ON MISCIBILITY WITH POLY(METHYL METHACRYLATE).** The improvement of the miscibility of poly(methyl methacrylate) (PMMA) and poly(vinyl chloride) (PVC) with moderate chlorination of PVC was demonstrated by determination of cloud-point curves and glass transitions of the mixtures. Heats of mixing of low-molar-mass analogues for PMMA and for the various structural units present in chlorinated PVC (CPVC) were determined in a microcalorimeter along with Fourier transform infra-red spectroscopy of these mixtures. The results show that the improvement of miscibility is caused by a specific interaction between the carbonyl group of PMMA and predominantly the CHCl group of CPVC. The decrease in miscibility observed when more strongly chlorinated PVC is used can be ascribed to the relatively high concentration of CCl<sub>2</sub> groups, which have a less favorable interaction with the carbonyl groups. (Edited author abstract) 24 refs.

**082500 STRUCTURAL FEATURES AND PROPERTIES OF POLYMER MIXTURES IN THE LAMINATION REGION.** Experimental and theoretical results are systematized regarding the laws governing the lamination process in polymer-polymer systems in the transitional region between the binodal and spinodal lines. An explanation is given for the drop in viscosity in the region and it is proposed that the observed laws are a consequence of differences between the conditions of segregation of macromolecules of the polymer components forming the mixture and segments of these molecules in the interphase layer. It is shown that a characteristic

feature of the liquid-liquid phase transition in polymer-polymer systems is that the macromolecules segregate at a point on the binodal line, while their segments remain fully compatible. The macromolecular segments also begin to segregate with a further change in external conditions, this segregation corresponding to a point on the spinodal line - the transition of the system to a normal unstable emulsion. (Edited author abstract) 10 refs.

**082501 MORPHOLOGY CONTROL OF BINARY POLYMER MIXTURES BY SPINODAL DECOMPOSITION AND CRYSTALLIZATION. 2. FURTHER STUDIES ON POLYPROPYLENE AND ETHYLENE-PROPYLENE RANDOM COPOLYMER.** Morphology control of binary polymer mixtures through spinodal decomposition and crystallization was studied by using polypropylene and ethylene-propylene random copolymer as a model system. A criterion for conservation of the modulated structure developed in the demixing liquid during and after the crystallization is discussed, and the locking-in phenomenon of the demixing processes by crystallization is clearly presented in some certain cases and was found to be responsible for the conservation of the structure existing in the liquid. (Edited author abstract) 10 refs.

Inaba, Nobuyuki (Idemitsu Petrochemical Co, Ichihara City, Jpn); Yamada, Takeshi; Suzuki, Shyunichi; Hashimoto, Takeji. *Macromolecules* v 21 n 2 Feb 1988 p 407-414.

**082502 DISTRIBUTION OF INTERACTIONS IN BINARY POLYMER MIXTURES: A MONTE CARLO SIMULATION STUDY.** Phase transitions from miscibility to immiscibility were observed in simulations of binary polymer mixtures on a planar square lattice using reptation sampling techniques. The relationship between the phenomenological interaction parameter,  $\chi$ , and the true molecular interaction energy was followed, and the dependence of the number and distribution of heterocontacts in the mixture on the applied heterosegment interaction energy was determined. Deviations from the results of mean-field treatments, which overestimate the number of heterocontacts, were observed even for athermal mixtures. Kinetically driven hysteresis governed by a temperature equilibrium time scale was examined for the phase transitions. An important prediction of expansion of the polymer chains in the miscibility region can be made on the basis of the results of chain end-to-end distance calculations. (Author abstract) 16 refs.

**082503 MODEL MIXING OF POLYMER MATERIAL.** Relationships among shape of mixer, mixing condition, and mixing performance for polymer material were experimentally investigated using three model mixers. Mixing parameters that could link quality of mixture with mixer shape and mixing condition were determined from analysis of model mixing. High-performance mixers have been developed through these investigations. (Author abstract) 7 refs. In Japanese.

Asai, Toshihiro. *R&D Res Dev Kobe Steel Ltd* v 38 n 2 Apr 1988 p 42-45.

**082504 MISCIBILITY OF POLY(VINYL METHYL ETHER) WITH STYRENE-METHYL METHACRYLATE COPOLYMERS.** The miscibility of poly(vinyl methyl ether) (PVME) with a series of styrene-methacrylate copolymers was studied. It was found that the critical copolymer composition for achieving miscibility with PVME at room temperature was about 60 mol% styrene. The blends underwent phase separation at elevated temperatures, but the LCST passed through a maximum as the methyl methacrylate content of the copolymer was increased. The maximum value of LCST exceeded that of the PS-PVME pair. The significance of the observed

miscibility window is discussed in terms of recent theories. (Author abstract) 17 refs.

**082505 NEW MATRIX RESINS FOR STRUCTURAL COMPOSITES.** Synthetic organic polymers need fiber reinforcement to improve their strength, stiffness, toughness and creep resistance. The maximum strength and stiffness are obtained when continuous fibers are aligned parallel with the applied load. Compromise is also necessary in the selection of the matrix. The matrix can consist of a mixture of two polymers. New methods of crosslinking involve: epoxide rings, vinyl or ethylenic unsaturation, acetylene groups, cyanide groups, and isocyanate groups. 7 refs.

Pritchard, Geoffrey (Kingston Polytechnic). *Plast Rubber Int* v 13 n 2 Apr 1988 p 26, 28-31.

**082506 ANALYSIS OF THE THERMODYNAMIC COMPATIBILITY OF INTERPENETRATING NETWORKS DURING THEIR SYNTHESIS.** A thermodynamic analysis of interpenetrating polymer networks (IPNs), at any extent of reaction during their synthesis, is presented for both simultaneous and sequential procedures. A model IPN is assumed to be built up by the independent stepwise homopolymerization of two monomers: a tetrafunctional one,  $A_4$ , and a trifunctional one,  $A_3$ . No reaction of copolymerization or grafting is allowed between the two types of polymers. For the case of semi-IPNs,  $A_3$  is replaced by  $A_2$ , i.e., a bifunctional monomer leading to a linear polymer. The free energy of mixing is described by a Flory-Huggins lattice model, whereas the elastic contribution is calculated by assuming affine deformation of an ideal elastic network. Results show that a sequential polymerization gives a more incompatible system (i.e., it enters the metastable region at lower conversions) than a simultaneous polymerization starting from the same monomers. (Edited author abstract) 18 refs.

**082507 GLASS TRANSITION OF POLYMERS MADE FROM SLURRIES OF POLY(ETHYL METHACRYLATE) AND METHYL METHACRYLATE.** Some biomedical materials are made from a slurry of a polymeric powder and a liquid methacrylate monomer. Conveniently, at the processing stage, the monomer acts as a plasticizer before it is polymerized to provide a service product. The question addressed here is whether products made from poly(ethyl methacrylate) (PEMA)/methyl methacrylate (MMA) slurries are miscible. Slurry systems PEMA and MMA yield rather homogeneous products on free radical polymerization, despite the immiscibility of PEMA and poly(methyl methacrylate). It is not known whether homogeneity is due to limitations on microphase separation by entanglements or to compatibilization by graft polymer formation. In any event, the products are inherently unstable and undergo phase separation on heating. 20 refs.

**082509 MODIFICATION OF CROSSLINKED POLY-(2,6-DIMETHYL-1,4-PHENYLENE OXIDE) WITH LARGE CYCLIC AND LINEAR POLY-(DIMETHYL-SILOXANE).** Poly-(2,6-dimethyl-1,4-phenylene oxide) (PPO) can be crosslinked by reacting selectively the methyl groups with N-bromo-succinimide and condensing the bromide with ethylene diamine splitting out hydrogen bromide. This can be done in the presence of large poly(dimethyl siloxane) rings composed of 92 repeating units. Approximately 26% by weight of the cyclics can be threaded and permanently captured by the polymer network producing a polymeric catenane. The author has also synthesized the pseudo IPN (or semi IPN) crosslinked PPO and linear poly(dimethyl siloxane). He compares the physical properties of this material with the polymeric catenane. **082510 <sup>13</sup>C NUCLEAR MAGNETIC RESONANCE SPECTRAL STUDY ON THE DISTRIBUTION OF SUBSTITUENTS IN RELATION TO THE PREPARATION METHOD OF PARTIALLY ACETYLATED DEXTRANS.** <sup>13</sup>C nuclear magnetic resonance (n.m.r.) spectra of partially modified dextrans with acetyl groups prepared by reaction with acetyl chloride or acetic anhydride in the homogeneous phase were analyzed at 75.4 MHz. It was found that the distribution of substituents in the anhydroglucose units of these partially acetylated dextrans can be estimated from their ring carbon spectra. The results showed that for acetylated dextrans prepared by reaction with acetyl chloride, the reactivity of individual secondary hydroxyl groups decreases in the order C-2 > C-4 > C-3. For these modified dextrans prepared with acetic anhydride, the ease of acetylation was C-2 > C-3 > C-4. The results were explained by considering the formation of intramolecular hydrogen bonds as well as by steric considerations. (Author abstract) 24 refs.

**082511 TOUGHENING BISMALEIMIDE RESINS BY REACTIVE LIQUID RUBBERS.** The modification of bismaleimide resins with carboxyl-terminated butadiene-acrylonitrile rubbers (CTBN) was studied. The effects of the rubbers on mechanical and thermal properties such as flexural strength, tensile strength, fracture toughness, glass transition temperature, and decomposition temperature of the rubber-modified bismaleimide resins are discussed. The morphology of these resins were investigated by means of scanning electron microscopy and dynamic mechanical analysis. Addition of the rubbers improved the toughness of the bismaleimide resins without significant reductions in heat resistance of the resins. (Author abstract) 20 refs.

**082512 CHEMICAL MODIFICATION OF POLY(2,6-DIMETHYL-1,4-PHENYLENE OXIDE) VIA PHASE TRANSFER CATALYSIS.** The chemical modification of poly(2,6-dimethyl-1,4-phenylene oxide) (PPO) has been performed under phase transfer catalyzed (PTC) conditions. Four types of reactions: Williamson etherification, cyanide displacement, esterification, and heterocyclic group transfer have been identified as positive reactions involving the nucleophilic displacement on PPO. In reaction with alcohols, under PTC conditions, functional yields as high as 100% were obtained while for the esterification reaction functional yields of 92% were

reached. Low conversions were found in reactions with cyanides and heterocyclic compounds. (Edited author abstract) 18 refs.

**082513 BOUNDARY INTEGRAL EQUATIONS FOR ANALYZING THE FLOW OF A CHOPPED FIBER REINFORCED POLYMER COMPOUND IN COMPRESSION MOLDING.** The flow of a chopped fiber reinforced polymer compound during compression molding is analyzed as a transient moving boundary problem. A special boundary integral formulation is used to calculate flow front velocities. The derivation involves the determination of fundamental solutions for the newly developed equations of motion. A generalized Green's formula is used in conjunction with these solutions to produce the final expressions which incorporate the boundary tractions and velocities directly. The major advantage in adopting a boundary integral approach is that there is no need to solve for interior pressures and velocities. An approximate boundary element representation of the basic integral equations is used to predict flow front progression for elliptical and rectangular charges. Based on a comparison with available analytic solutions for the elliptical charges, we conclude that the method performs well over the entire range of physical and geometric parameters. A further examination of numerical solutions shows that practical convergence can be obtained for both quadratic and constant boundary elements with moderate mesh spacings. **082515 DISTRIBUTED MODEL OF FLOW IN SPIRAL MANDREL DIE.** Spiral mandrel dies are widely employed in the processing of polymeric films in the blown extrusion process. The flow dynamics in spiral mandrel dies is modeled in conjunction with a lubrication assumption. The model permits the determination of velocity, rate of deformation, shear stress, and first normal stress difference distributions. It should generate a better understanding of the thermomechanical history experienced by polymeric melts during extrusion in spiral mandrel dies, and should thus facilitate better die design and/or optimization of operating conditions. **082516 DETERMINATION OF THE STRUCTURE OF POLYETHYLARYLMETHYLENES BY <sup>13</sup>C NUCLEAR MAGNETIC RESONANCE SPECTROSCOPY.** Ethyl-substituted polyarylmethylenes have been prepared by reacting ethylbenzene with bis(chloromethyl)benzene (BCMB) under Friedel-Crafts conditions. The nature of the substitution patterns in the aromatic rings has been established using <sup>13</sup>C Fourier transform nuclear magnetic resonance spectroscopy. The ethyl groups can be used to distinguish between those benzene rings derived from ethylbenzene and those from BCMB and can thus facilitate an understanding of polymerization mechanisms. The structure of the products consists of di-, tri- and tetra-substituted benzene rings. (Edited author abstract) 10 refs.

**082518 EVALUATION OF THE ORIENTATION OF NON-CRYSTALLINE POLYMERIC CHAINS WITH A POLARIZED FLUORESCENCE METHOD.** The polarized fluorescent intensity is affected by two factors: the optical properties of the optically biaxial substance, which give rise to extraordinary lights in the sample, and the molecular structures of the optically anisotropic polymer solid dyed with fluorescent dyestuff. The effects of these factors on this intensity are introduced into formulae used for evaluating the molecular orientation. In these formulae, the fluorescent intensity has been expressed in terms of measurable values by separating into two terms: one depends on the molecular orientation and the other concerns the nature of the molecular structures and the device of optical measurement. It has thus been possible to pick up the terms associated with the fourth moment of direction cosines of the non-crystalline molecular chain axis. How the electric amplitude difference between the refracted extraordinary lights influences the fluorescent intensity is also considered. (Author abstract) 10 refs. In Japanese.

**082520 LIQUID CRYSTALLINE POLYMERS.** Just recently it was found possible to produce polymers using the structural principles of liquid crystalline compounds. The resulting materials have, as expected, unusual proper-

ties. Numerous applications, not only in opto-electronics, are already anticipated for such materials. The intention of this article is to show, with a knowledge of the structural principles of low molecular weight liquid crystals, how various types of polymers with potentially liquid crystalline phases can be synthesized. Each structural type shows in specific ways the liquid crystalline phase and the properties of the polymer. The peculiarities of selected examples are outlined and their properties and application perspectives discussed. 54 refs.

**082521 INTERPRETATION OF LIGHT SCATTERING FROM SUPERMOLECULAR STRUCTURES IN LIQUID SYSTEMS BY MASTER CURVES.** By a detailed analysis of light scattering curves, a more complete characterization of colloidal particles may be achieved. For this purpose, a fitting procedure based on theoretical master curves for models of polydisperse systems of homogeneous spheres and Gaussian coils is presented. The use of a suitable logarithmic distribution function makes it possible to separate the influence of polydispersity from that of particle size on the shape of the scattering curve. A double logarithmic plot of master curves reduces the fitting procedure to translations of the experimental curves. The reliability and accuracy of this procedure are demonstrated by light scattering results on solutions of a polyelectrolyte complex with variation of salt content. (Author abstract) 18 refs.

**082522 MOLECULAR STRUCTURE AND PHOTOREACTION OF POLY(METHYLPROPYLSILANE).** The molecular structure and photoreaction of poly(methylpropylsilane) (PMPrS) are investigated. The <sup>29</sup>Si-NMR spectra reveal that PMPrS is a linear polymer with no branches. Fine multiple splitting of <sup>29</sup>Si-NMR is observed at room temperature. This multiple splitting is thought to be due to molecular conformation. The photo-oxidation reaction of the PMPrS film is found to be caused by light irradiation at the UV absorption band, 330 nm. Quantum efficiencies of scission and crosslink related to photodegradation are evaluated. There is little difference in either the molecular structure or photoreactivities between the high and the low molecular weight portions of the bimodal molecular weight distributions of PMPrS. (Author abstract) 21 refs.

**082528 DIPOLE MOMENT AND CONFORMATIONAL ANALYSIS OF ITACONATE POLYMERS.** The dipole moments ( $\mu$ ) of poly(monobenzyl itaconate) (PMBzI), and of poly(dibenzyl itaconate) (PDBzI), of known tacticity ( $w_m$ ), have been determined in dioxane at  $25^\circ\text{C}$ :  $\mu = 1.96\text{ D}$ ,  $w_m = 0.50$  (PMBzI); and  $\mu = 1.52\text{ D}$ ,  $w_m = 0.25$  (PDBzI). The dipole moment and the unperturbed dimensions (characteristic ratio,  $C_\infty$ ) of polyitaconate chains are calculated theoretically, as a function of polymer tacticity, by matrix multiplication

methods. The polymer  $\mu$  calculated is scarcely sensitive to tacticity. Comparison with experimental  $\mu$  shows excellent agreement in the case of PDBzI. For PMBzI, the experimental  $\mu$  is higher than calculated, and agreement requires modification of the conformational parameters (but within the precision limits of the calculation). (Edited author abstract) 44 refs.

**082530 PLASTIC DEFORMATION OF POLY(TETRAMETHYLENE OXIDE).II. MOLECULAR ORIENTATION AS MEASURED BY X-RAY DIFFRACTION AND NMR MEASUREMENTS.** The orientation of the crystalline and amorphous phases in uniaxially drawn samples of polytetramethylene oxide has been studied by x-ray and NMR methods. Pole figure measurements give the orientation of the crystalline phase. Its dependence on the draw ratio does not obey the pseudoaffine model. The crystalline fraction is derived from NMR measurements at temperatures between  $T_g$  and  $T_m$ , where the free induction decay (FID) of the unoriented sample can be analyzed in terms of a rigid (crystalline) phase, a constrained phase, and an amorphous phase. Low temperature ( $T < T_g$ ) measurements of the NMR second-moment anisotropy in protonated and deuterated samples give a mean orientation of the chains higher than that corresponding to the crystalline phase. The lack of anisotropy in the tail of the FID at temperatures between  $T_g$  and  $T_m$  indicates no appreciable anisotropy in the truly amorphous interlamellar phase. From this and from the ratio of the  $P_4/P_2$  orientations, factors which obey the 'most probable distribution', it is concluded that the amorphous orientation is due to the layer of constrained chains at the surface of the lamellae. (Edited author abstract). 17 refs.

**082532 ANALYSIS OF THE ACCURACY OF DETERMINING MOLAR-MASS AVERAGES OF POLYMERS BY GPC WITH AN ON-LINE LIGHT-SCATTERING DETECTOR.** The effect of errors of concentration and molar-mass detectors in GPC on the accuracy of determining molar-mass averages  $M_n$  and  $M_w$  was analyzed. Model calculations show that by means of GPC with an on-line low-angle laser light-scattering (LALLS) photometer only  $M_w$  can be determined with acceptable accuracy.  $M_n$  can be determined with acceptable accuracy only for polymers that have very small polydispersities.  $M_n$  can be determined with greater accuracy from data of a concentration detector and chromatographic-column-calibration data. The most suitable procedure for the determination of  $M_w$  seems to be a direct integration of the molar-mass detector output, even if the error due to neglecting the second virial coefficient term is significant. Compared with the inaccuracy of detectors, axial dispersion appears not to be the main source of errors in GPC with an on-line molar-mass detector. (Author abstract) 10 refs.

**082535 MOLECULAR WEIGHT DISTRIBUTION CONTROL IN A BATCH POLYMERIZATION REACTOR.** This paper proposes a new method for getting the reactor temperature and initiator concentration in order to obtain a final product of polymer which has a prescribed molecular weight distribution (MWD) in a free-radical polymerization batch reactor. At first, profiles of instantaneous average chain length and polydispersity are obtained so as to get the desired MWD. Next, time

profiles of reactor temperature and initiator concentration are determined from the profiles of instantaneous average chain length and polydispersity based on the mathematical model of the reactor. As the final step, the time profile of reactor temperature is realized by the Adaptive Internal Model Controller (AIMC) developed by us. (Edited author abstract) 13 refs.

**082536 NEW HORIZONS FOR LATEX.** The making of water borne multicomponent polymer systems (MPS), both as latices and reactive oligomers, creates new opportunities for developing polymers with enhanced performance to meet the needs of the future. Much developmental activity is now being conducted to provide water-borne reactive oligomers since starting at a low molecular weight and building in-site can meet certain demands where the high new resins, because of their high molecular weight, cannot penetrate and wet certain surfaces. Highly innovative process and formulation techniques have engineered some latex systems that dry in three to eight seconds and gel in eight minutes - far faster than solvent systems. The resulting film is waterproof because there is no free surfactant or soap to rewet.

**082537 MOLECULAR-WEIGHT DISTRIBUTIONS OF POLYMERS BY THERMAL FIELD FLOW FRACTIONATION WITH EXPONENTIAL TEMPERATURE PROGRAMMING.** Thermal field flow fractionation (TFFF) is a promising quantitative method for determining the molecular-weight distribution (MWD) of polymers. Separations are carried out by applying a thermal gradient across a single flowing mobile phase in a thin, highly polished channel formed with parallel plates. Wide MWD's are conveniently characterized by the technique of time-delay, exponential-decay TFFF (TDE-TFFF). This approach produces a linear calibration plot of log MW vs retention time for accurate MWD measurements. Accuracy of the method is limited only by the quality of the standards required for the calibration. (Edited author abstract) 14 refs.

**082538 ONE-POINT METHOD TO CALCULATE MOLECULAR WEIGHT FROM LOW-ANGLE LASER LIGHT SCATTERING DATA. I. APPLICATION TO ACRYLAMIDE POLYMERS.** A new method for the calculation of the weight-average molecular weight from low-angle laser light scattering data has been developed which only requires the measurement of the Rayleigh factor at a single concentration. The method requires the knowledge of the dependence of the second virial coefficient on molecular weight and has been applied to polyacrylamides ranging in molecular weight from 10,000 to 9,000,000. The new method improves the accuracy of light scattering measurements to  $\pm 4.7\%$  compared with  $\pm 11.2\%$  for the conventional procedure and requires only one-fourth the time. The effect of polydispersity has been included in the procedure. The method is general and is recommended for all linear polymers. (Author abstract) 40 refs.

**082539 DETERMINATION OF NUMBER-, WEIGHT-, AND Z-AVERAGE MOLECULAR WEIGHTS BY MENISCUS-DEPLETION SEDIMENTATION EQUILIBRIUM.** Sedimentation equilibrium (SE) in the analytical ultracentrifuge, unlike most other absolute methods of molecular weight determination, can in principle provide several types of average molecular weight for a polydisperse polymer. In practice,

however, this potential has not been fully realized. In this note it is demonstrated that a long-column meniscus-depletion SE procedure is of value for the determination of number-, weight- and z-average molecular weights. This method is applied to the National Bureau of Standards' (NBS) polystyrene sample 706, which has a broad distribution of molecular weights. 13 refs.

**082540 CHARACTERIZATION OF POLYMER MOLECULAR WEIGHT DISTRIBUTION BY TRANSIENT VISCOELASTICITY: POLYTETRAFLUOROETHYLENES.** The relationship between the relaxation time spectrum  $H(\tau)$  in the terminal zone and the volume-fraction differential molecular-weight-distribution function  $P(M)$  is derived by considering binary chain contacts for stress transmission. This is used to determine the molecular-weight-distribution curves from the stress relaxation modulus spectrum (above the crystal melting point) at  $370^\circ\text{C}$  for a number of commercial and experimental poly(tetrafluoroethylenes) (PTFEs). It is found that PTFEs typically have bimodal molecular-weight distributions. The lower-molecular-weight peak conforms essentially to the 'most-probable' distribution, and the higher-molecular-weight peak to the binary coupling distribution. The entanglement molecular weight  $M_e$  is 5490, and the number of main-chain atoms between entanglement points is 110, consistent with a flexible chain. (Edited author abstract) 19 refs.

Wu, Souheng (DuPont, Wilmington, DE, USA). *Polym Eng Sci* v 28 n 8 Apr 1988 p 538-543.

**082541 ROLE OF EXCLUDED VOLUME IN THE CONFIGURATIONAL PROPERTIES OF UNIFORM STAR POLYMERS: ITERATIVE CONVOLUTION AND MONTE CARLO SIMULATION.** The dimensional properties of three-dimensional uniform athermal self-avoiding star polymers of small to intermediate molecular weight are determined in the iterative convolution (IC) approximation. The results are compared with continuum Monte Carlo (MC) simulations and with lattice-based and renormalization group (RG) estimates that relate to the large-N limit. In particular, the present analysis provides direct structural and dimensional assessment of the interior star regimes proposed by M. Daoud and J.P. Cotton, which are inaccessible to the lattice-based and RG treatments. We find no evidence to support the Daoud-Cotton proposals. On the basis of the iterative convolution approximation, the central core structure of the star terminates at a density discontinuity followed by secondary radial structural features. **082542 EFFECT OF HIGH MOLECULAR WEIGHT POLYETHYLENE OXIDE ON THE STRUCTURE AND PROPERTIES OF POLYPROPYLENE FIBRES.** The effect of micro amounts of PEO with  $M=4 \times 10^6$  and  $5 \times 10^6$  on the structural features and properties of PP fibers has been studied. On addition of 0.15-0.2 percent PEO slight rise in fluidity is observed linked with increase in the degradation of the melt, decline in orientation of the macromolecules and a slight fall in the degree of crystallinity and melting point of the fibers. Pigment is also a component which may change the pseudoplasticity of the melt due to the structure resulting from its agglomeration and steric immobilization. (Author abstract) 6 Refs.

**082543 EFFECT OF THE INITIATOR ACETYL PERCHLORATE UPON THE MORPHOLOGY, KINETICS AND MECHANISMS OF CRYSTAL GROWTH OF POLY(OXYMETHYLENE).** The kinetics of the cationic polymerization of trioxane initiated by different concentrations of acetyl perchlorate in dichloromethane solution is analyzed. Hexagonal single crystals of poly(oxyethylene) (POM), are obtained after an induction period. The kinetic of the crystal growth have been followed by electron and light microscopic techniques. The influence of the initiator concentration on the morphology of the POM-crystals, together with the fact that the initiator is adsorbed on the crystal surface, enabled the discussion of possible reaction mechanisms of polymerization and crystallization. **082546 MORPHOLOGICAL STRUCTURE OF A POLYMER COATING ON POLYMERIZATION-MODIFIED FILLERS.** The morphological types of a polymer coating on mineral fillers for the polymerization modes of modification carried out by radical polymerization of vinylchloride in presence of fillers have been investigated and reviewed. From the results it follows that the morphology of the polymer coating of PVC on fillers in all variants of polymerization modification is determined by the conditions of polymerization. The main factors influencing the morphology of the coating are the site of the polymerization reaction, the nature of the interaction of the coating with filler and the structure of the filler surface. The reaction site determines the basic type of morphology of the coating - smooth or granular - while different combinations of this factor with the nature of interaction between polymer coating and filler and the structure of the filler itself lead to the variety of morphological forms of coatings. (Edited author abstract) 6 refs.

**082548 PHASE MORPHOLOGY OF A MODEL POLYBLEND.** The systematic study of the melt mixing process and its effects on the phase morphology and melt properties were carried out on a model polyblend and polyalloy. The polyblend consisted of PE-LD and PS at a 70:30 ratio, respectively. The corresponding polyalloy contained an additional five parts of SEB block co-polymer to act as a compatibilizing agent. The experiments were made on six different brands of industrial compounding extruders under well defined process parameters. The authors report on the preliminary yet quantitative relationships between the mixing process, melt rheology and the related phase morphology as found on the twin screw extruder type ZE 40. It is shown that these results will allow a strategy to be developed for controlling the mixed process during the creation of polyblends, by selecting the proper geometries in compounding extruders. Results indicate a good correlation between the shear stress and the domain size of the minor phase as predicted from the software Simulblend. In English and German.

**082549 INCORPORATION OF MOLECULAR ORIENTATION INTO SYSTEM OF LAMELLAR MORPHOLOGY. 1. EFFECT OF PACKING ENTROPY ON THE LAMELLAR THICKNESS OF BLOCK COPOLYMERS.** Equations for the dimensions of the A and B regions of monodisperse diblock copolymers with lamellar morphology are obtained. An important feature of the treatment is the incorporation of the orientation-dependent packing entropy into the formalism. The equations are believed to be accurate over the whole range of orientation of bonds, from random orientation to perfect alignment. Copolymer thicknesses vary as the 2/3 power of molecular weight to the first power depending on the amount of orientation induced by the packing entropy and the energetics. The amount of bond orientation in stretched molecules in bulk material is twice what the molecules would have if they were stretched (by the same stretch ratio) in solvent. (Edited author abstract) 42 refs.

## Nitration

**082550 YELLOWING MECHANISM OF AROMATIC URETHANES AND UREAS EXPOSED TO NO<sub>x</sub> GAS AND ACTION OF ANTIYELLOWING AGENT.** Model systems using phenyl isocyanates and 4,4'-diphenylmethane diisocyanates (MDI) were investigated to analyze the nitrogen oxides (NO<sub>x</sub>) induced yellowing mechanism of aromatic polyurethane and polyurea. Nitrations of aromatic rings, especially those of p-position of the urethane and urea linkages, play an important role of the NO<sub>x</sub> induced yellowing. The bond cleavage at the central methylene bridge of MDI molecule took place with nitrations of the benzene rings, and some high molecular weight products were formed. The mechanism of the stabilization of polyurethane and polyurea against the NO<sub>x</sub> induced yellowing was also studied. Tertiary amines and magnesium oxide were found to be

efficient stabilizers of these polymers against the NO<sub>x</sub> induced yellowing. These stabilizers reacted very rapidly with NO<sub>x</sub> and efficiently converted to inactive compounds for the yellowing. The experimental results show that these stabilizers really act as good chemical absorbers of NO<sub>x</sub> within the polymers. 7 refs. In Japanese.

**082552 EFFECT OF THE SIZE OF STRUCTURAL BULK INHOMOGENEITIES ON THE SPECULAR TRANSMITTANCE OF POLYMER FILMS.** This paper is confined to the effect of optical inhomogeneities in polymer films on the scattering or specular transmittance of light. Potential causes for the presence of scattering entities in the bulk phase of polymers are discussed. It is shown that practical transmittance measurements are greatly influenced by the angular width of the instrument receptor aperture. The choice of larger receptor apertures will tend to include some of the scattering at small angles due to large inhomogeneities in the measurement of specular transmittance. As a consequence, the transmittance measured is not necessarily increased by reducing the size of the inhomogeneities in the polymer films, but there is a critical size when the specular transmittance is a minimum. (Author abstract) 22 refs.

**082553 SPECULAR REFLECTANCE PROPERTIES OF SILVERED POLYMER MATERIALS.** The specular reflection properties of transparent cast polymer sheets and extruded polymer films, silvered and unsilvered, have been characterized with a newly designed specular reflectometer. The results obtained with this instrument are either absolute reflectance or a measure for the Fourier transform of the reflection function of the specimen in one dimension. Cast polymer sheets are investigated before and after silvering, and silvered polymer films are evaluated by mounting them with an adhesive onto aluminum or glass substrates, or by suspending the thin, silvered polymer as a taut membrane. Silvered polymers have attained a specularly such that over 90% of the incident beam is contained in a 1-2 mrad full-cone angle when mounted on a good substrate or suspended as a membrane. This value is well within the current goals for solar concentrators but silvered polymer mirrors are currently less specular than glass mirrors. The image quality of these mirrors does not change significantly over the wavelength range 400-1000 nm and angles of incidence between 20° and 60°. A principal limiting factor to the initial specularity of the polymer mirrors was waviness and/or curvature of the surface. Hence, the material being used as a substrate plays an important role in the optical performance of the mirror. (Edited author abstract) 17 refs.

**082554 INFRARED ACTIVITY OF PHOTOEXCITATIONS IN POLYTHIOPHENE.** A careful measurement of the photoinduced infrared absorption of polythiophene is reported. The observation of new spectral features below the level of previous doping and photogeneration experiments provides evidence for weakly infrared active bipolaron shape oscillations predicted by recent calculations based on the continuum model for conjugated polymers. In addition, four new photoinduced absorptions, not described by existing theories for defect vibrations, demonstrate the coupling of photogenerated charged nonlinear excitations to ring vibrations of the aromatic thiophene monomer. (Author abstract) 25 refs.

**082555 THERMOCHROMIC AND SOLVATOCHROMIC EFFECTS IN POLY(3-HEXYLTHIOPHENE).** We report thermochromic and solvatochromic effects in the soluble conductive polymer poly(3-hexylthiophene). Thin solid films of the polymer change color at higher temperatures. The color of solutions of the polymer can be changed by varying the composition of the solvent. Optical absorption in good solvents is similar to that of thin solid films at higher temperatures, while in poor solvents, absorption features similar to those found in solid films at low temperatures are observed. We discuss these effects with reference to the existence of a hitherto disregarded type of conformational defect, conformons. (Edited author abstract) 26 refs.

**082556 COULOMB INTERACTION AND OPTICAL SPECTRA IN CONJUGATED POLYMERS.** Solitonic excitations in conjugated polymers are studied under the influence of Coulomb interactions. In addition to stabilizing bipolarons these effects change the characteristics of the optical spectra. The results are compared with recent experiments in polythiophene and good agreement is found. (Edited author abstract) 11 refs.

**082557 INTERCHAIN OPTICAL TRANSITIONS IN CONDUCTING POLYMERS.** Interchain optical absorption ( $\alpha_I$ ) in oriented conducting polymers is found to depend significantly on the type of three-dimensional order in the dimerization pattern:  $\pi-\pi^*$  transitions are induced by E.I. light between out-of-phase chains, normally being suppressed for in-phase chains.  $\alpha_I$  is demonstrated to give large contribution to the photogeneration of long-lived charges if interchain hopping is non-adiabatic. The formation of interchain excitons (IE) for oppositely charged polarons or solitons on adjacent chains is considered to be due to strongly anisotropic Coulomb attraction. The optical creation of polaronic IE by E.I. and its conversion into solitonic IE in trans-(CH)<sub>x</sub> are discussed. (Edited author abstract) 36 refs.

**082558 OPTICAL ABSORPTION FROM POLARONS AND BIPOLARONS IN POLYTHIOPHENE.** The authors present a theoretical calculation, within the one-electron Hückel model, of the optical absorption due to polarons and bipolarons in doped polythiophene. The results are used to describe the absorption spectra at

thermal equilibrium, when the two kinds of excitation are present. Comparison with experimental data obtained in the case of doping shows that the Coulomb effects must be taken into account and the binding energy to the dopant is estimated to be about 0.14 eV. Although the bipolaron still remains the lowest-lying charged excitation, the contribution of Coulomb effects is shown to increase the proportion of polarons at thermal equilibrium. (Edited author abstract) 25 refs.

**082561 CIRCULAR DICHROISM BAND SHAPES FOR HELICAL POLYMERS.** Three approaches are discussed for handling band shapes in circular dichroism (CD) and absorption spectra calculations for helical polymers. The effect of interaction between chromophores upon polymer transition band shapes is explored by employing Gaussian band shapes for isolated chromophore transitions in the classical coupled oscillator scheme. The results are compared to those obtained from using Lorentzian band shapes and to those obtained by using  $\delta$  function line shapes that are replaced by Gaussians after interactions are taken into account. The three approaches yield very different calculated  $\pi^*$  absorption and circular dichroism spectra for an  $\alpha$ -helix. Skewing of band shapes derived from input Gaussians is analyzed by employing input bands that are composite bands of several Lorentzians and mimic the input Gaussians. Skewing is shown to result from coupling of different vibronic components. (Edited author abstract) 29 Refs.

**082563 NEMATIC ORDER OF SEMIFLEXIBLE THERMOTROPIC POLYMERS FROM NMR DATA. FURTHER DEVELOPMENTS OF A PREVIOUS ANALYSIS.** The approach adopted in a previous paper for interpreting the observed  $^2\text{H}$  NMR spectra of poly(oxyphenylene-carbonyloxyphenyleneoxydodecanediyl- $d_{20}$ ) in the nematic state is developed in order to take into account the different time scales affecting conformational jumps and uniaxial reorientations of the chain around the director. Results show that by decoupling these two kinds of motion, the model is no longer critical to geometry. A very local additional order parameter is in fact required and it accounts for all geometrical features which describe the connection of the spacer to the mesogen unit while the structure of the  $^2\text{H}$  NMR spectrum is solely determined by the conformational mobility of  $\text{CD}_2$  groups. (Author abstract) 6 refs.

**082568 REACTION OF 2,4-DINITROPHENYLHYDRAZINE WITH OXIDIZED POLYMERS: A CAUTIONARY NOTE.** The reaction of 2,4-dinitrophenylhydrazine (DNPH) with model hydroperoxides has been investigated. Under conditions typically employed for carbonyl determination in oxidized polymers, the hydroperoxides undergo acid-catalyzed rearrangement to form additional carbonyl groups which subsequently react with DNPH. The rearrangement is particularly efficient for tertiary allylic hydroperoxides, although even t-butyl hydroperoxide gives some 2,4-dinitrophenylhydrazone. (Author abstract) 23 refs.

Boon, Andrew J. (Malaysian Rubber Producers' Research Assoc, Hertford, Engl). *Polym Commun (Guildford Engl)* v 29 n 2 Feb 1988 p 45-47.

**082569 KINETIC MODEL OF THE MECHANISM OF HIGH-TEMPERATURE INHIBITED OXIDATION OF POLYMERS.** A kinetic model has been presented for the mechanism of the inhibited autooxidation of polymers. In addition to the reaction of the peroxide radical  $\text{RO}_2^\cdot$  with the radical  $\text{In}^\cdot$  (stage 8) and the molecule  $\text{InH}$  (stage 7) of the inhibitor, which are typical of this process, the model also involves kinetic chain propagation by the radical  $\text{In}^\cdot$  (stage 10). Theoretical analysis of the model has been performed, which shows the basic difference between the model and the conventional kinetic schemes of inhibited oxidation in which the  $\text{RO}_2^\cdot + \text{InH}$  reaction (stage 7) is considered to be the kinetic chain termination step. The model allows the quantitative description of the inhibited autooxidation in general, viz. the kinetic curves of oxygen absorption and hydroperoxide accumulation during induction, inhibitor consumption and the concentration dependence of induction. The fact that the model fits the real process adequately is corroborated by the quantitative and qualitative agreement between calculations and experimental data on the oxidation of polyethylene in the presence of various spatially-hindered phenols and that of polypropylene in the presence of Nonox WSP. (Edited author abstract) 25 refs.

**082570 THERMOCONTROL OF ELECTRON TRANSPORT THROUGH TERNARY COMPOSITE MEMBRANES COMPOSED OF POLYMER/LIQUID CRYSTAL/ELECTRON CARRIERS.** We selected vitamin  $\text{K}_1$  and hydrophobic viologen as electron carriers (ECs) and prepared ternary composite membranes composed of polymer/liquid crystal/EC. As reference membranes we used polymer/dibutyl phthalate/EC membranes which have no phase transition at the experimental temperature range. The redox-coupled electron transport for the vitamin  $\text{K}_1$  mediated system is illustrated. We have found that the rate of electron transport across the polymer/CPB/EC membranes changes distinctly at the crystal-liquid crystal phase transition temperature of CPB, and that the rate of electron transport can be controlled by an on-off-type temperature switch. 21 refs.

Shinkai, Seiji (Nagasaki Univ, Nagasaki, Jpn); Shimamoto, Katsuhiko; Nakamura, Shinichiro; Manabe, Osamu; Kajiyama, Tisato. *J Polym Sci Part C* v 25 n 12 Dec 1987 p 495-501.

**082571 GAS TRANSPORT IN POLYMERS BASED ON BISPHENOL-A.** Permeation measurements for  $\text{CO}_2$ ,  $\text{CH}_4$ ,  $\text{O}_2$ ,  $\text{N}_2$ , and He were made with three polymers based on bisphenol-A, namely a polyhydroxyether, a polyetherimide, and a polyarylate. Measurements were also made for  $\text{CO}_2$  and  $\text{CH}_4$  in polysulfone. The data for  $\text{CO}_2$ ,  $\text{CH}_4$ , and  $\text{N}_2$  plus previous data for these gases in polycarbonate and polysulfone were combined with equilibrium gas sorption data and analyzed with the dual mode/partial immobilization model and the more recent gas-polymer-matrix model. A comparison of the two models was done on the basis of physical interpretations of the resulting parameters. The diffusion coefficient for the Henry's law population was related to the kinetic diameter of the gas. The infinite dilution, Henry's law population was related to the kinetic diameter of the gas. The infinite dilution, Henry's law, and Langmuir diffusion coefficients were related to the free volume of the polymer. The work suggests a means of order-of-magnitude estimation of diffusion coefficients from polymer density and molecular structure. (Author abstract) 28 refs.

**082572 GAS SORPTION IN POLYMERS BASED ON BISPHENOL-A.** Equilibrium gas sorption measurements for  $\text{CO}_2$ ,  $\text{CH}_4$ , and  $\text{N}_2$  were made with three polymers based on bisphenol-A, namely a polyhydroxyether, a polyetherimide, and a polyarylate. These data plus previous results for two other bisphenol-A polymers, polycarbonate and polysulfone, were analyzed using the dual-mode sorption model and the more recent gas-polymer-matrix model. The models were compared on the basis of physical interpretations of the unrelaxed volume of the glassy polymer. The Henry's law sorption parameter from the dual-mode model was related to the internal pressure of the polymer and to its tensile stress at yield. The work suggests a means for estimation of gas sorption levels from thermal and mechanical properties of the polymer. (Author abstract) 37 refs.

**082573 ON THE DUAL MODE GAS TRANSPORT MODEL FOR GLASSY POLYMERS.** The present paper is concerned with a detailed examination of the formalism and the physical basis of the dual mode mobility model used for the theoretical description of gaseous transport in glassy polymers in the light of recent theoretical and experimental work. It is shown that there are no really major differences among the original formulation of the model and later variants. A major modification becomes necessary, however, if the Langmuir sorption mode is assumed to exist in the form of patches or domains extensive enough to constitute a macroscopically recognizable phase rather than in the commonly accepted form of scattered individual adsorption sites. It is shown that the proper treatment of this case reduces to the familiar dual mode mobility formalism only under certain conditions. The interpretation of the experimental results thus far available is considered in some detail, and the usefulness of each of the aforesaid approaches in this respect is discussed. (Author abstract) 20 refs.

**082574 TEST OF A MODEL OF STRESS-DEPENDENT DIFFUSION BY MEANS OF COMBINED COLORED TRACER AND BIREFRINGENCE PROFILE MEASUREMENTS.** In the present paper we further test a model of stress-dependent diffusion previously used with success to simulate the variation from Case I to Case II penetration kinetics in the system liquid methylene chloride-uniaxially oriented cellulose acetate film, according to whether penetration occurs across or along the axis of preferred macromolecular orientation. Data on penetration rates, optical density profiles (using a colored tracer), and the corresponding birefringence

profiles, characteristic of these penetration modes in the aforesaid system, are presented and compared with appropriate model uptake kinetic curves and penetrant concentration and compressive differential swelling stress profiles. It is shown that the salient features of the observed experimental behavior are in general accord with model predictions based on physically realistic assumptions. (Author abstract) 19 refs.

**082575 APPLICATION AND DEVELOPMENT OF SYNTHETIC POLYMER MEMBRANES, PART III. SEPARATION OF WATER-ETHANOL MIXTURE THROUGH SYNTHETIC POLYMER MEMBRANES CONTAINING AMMONIUM MOIETIES.** The pervaporation technique through a membrane is considered to be one of suitable methods for separation of aqueous ethanol solution. Selective separation of aqueous ethanol solution has been attracting attention, since the formation of ethanol via fermentation of biomasses will be in the near future an important industrial process, which relates to the energy problem. In the present article, attention is focused on the selective separation of water from aqueous ethanol solution in terms of coulombic interaction. Membranes having ammonium moieties as cationic charge sites, quaternized poly[3-(N',N'-dimethyl)aminopropylacrylamide-co-acrylonitrile] membranes, were prepared and the selective separation of water-ethanol mixtures through the present membranes were investigated. 31 refs.

**082576 GAS PERMEABILITY OF POLY(ORGANOPHOSPHAZENES).** The gas permeability and oxygen to nitrogen selectivity were determined for some poly(organophosphazenes). The membrane having the highest gas permeability was  $[\text{NP}(\text{NPH}_2)_2 \text{NE}_2(2)]_n$ , which had  $1.5 \times 10^{-6} \text{ cm}^3 (\text{cm cm}^{-2}) \text{ s}^{-1} (\text{cm Hg})^{-1}$  to oxygen or  $2.2 \times 10^{-6} \text{ cm}^3 (\text{cm cm}^{-2}) \text{ s}^{-1} (\text{cm Hg})^{-1}$  to nitrogen. The membrane having the highest oxygen to nitrogen selectivity of about 3 had the formula  $[\text{N}(\text{OC}_6\text{H}_4\text{Cl-p})_2]_n$ . The selectivity did not depend on the glass transition temperature of the membranes. The membrane prepared from  $[\text{NP}(\text{PC}_6\text{H}_4\text{CH}_3\text{-p})_2]_n$  had a negative activation energy for oxygen and nitrogen permeability. (Author abstract) 9 refs.

**082577 GAS PERMEABILITY OF POLYVINYL-TRIMETHYLSILANE MODIFIED BY THE RADIATION GRAFTING OF ACRYLONITRILE.** The permeability and diffusion of a number of gases at 20-80°C through homogeneous membranes made from polyvinyl-trimethylsilane modified by the radiation grafting of acrylonitrile have been investigated. An increase in the proportion of PAN in the membranes leads to an increase in the selectivity of the permeability of pairs of gases such as  $\text{He-CH}_4$ ,  $\text{He-N}_2$ ,  $\text{He-CO}_2$  and  $\text{H}_2\text{-CH}_4$ . In the system studied, there is a correlation between the diffusion coefficient and the effective cross-section of the gas molecules and between the solubility coefficient and their characteristic force constants of the Lennard-Jones potential. (Author abstract) 9 refs.

Starannikova, L.E. (AV Topchiyev Inst for Petrochemical Synthesis, USSR); Teplyakov, V.V.; Durgar'yan, S.G. *Polym Sci USSR* v 28 n 6 1986 p 1411-1416.

**082578 INVESTIGATION OF THE HIGH GAS PERMEABILITY OF POLY(1-TRIMETHYLSILYL-1-PROPYLENE).** The permeability of poly(1-trimethylsilyl-1-propylene), PMSP, to light gases is higher than that of any other nonporous synthetic polymer at ambient

temperatures. PMSP is in the glassy polymer state at these temperatures. Permeability, diffusion, and solubility coefficients were determined for  $\text{N}_2$ ,  $\text{O}_2$ ,  $\text{CH}_4$ , and  $\text{CO}_2$  in PMSP, and are compared with values reported for these gases in poly(dimethyl siloxane). The higher gas permeability of PMSP results primarily from a substantial gas solubility, which appears to be due, in turn, to a large 'excess' free volume in the unrelaxed (Langmuir) domains of this glassy polymer. (Edited author abstract) 29 refs.

**082579 GAS TRANSPORT IN POLY(VINYL CYCLOHEXANECARBOXYLATE).** Low-pressure gas permeation measurements were performed on poly(vinyl cyclohexanecarboxylate) to evaluate its transport characteristics. The transport data of  $\text{CO}_2$ ,  $\text{O}_2$ ,  $\text{N}_2$ , He, and Ar were presented as a function of temperature ranging from 15 to 85°C. The apparent transport parameters were determined by the time lag method above and below the glass transition temperature and they were compared with other polymers of similar chemical structures. The side chain of the polymer has a bulky cyclohexyl group, which seemed to increase gas diffusivity. The activation energy for diffusion seemed to be related with the polarity of side chain. The relationships between gas diffusivity, physical properties, and chemical structure were qualitatively discussed in comparison with the data on poly(vinyl benzoate) and poly(vinyl acetate). (Author abstract) 17 refs.

**082580 QUANTITATIVE THEORY AND INTERPRETATION OF THE EXPERIMENTAL DATA ON THE COIL-GLOBULE TRANSITION IN THE PERSISTENT MACROMOLECULE.** The theory of the globular state and the coil-globule transition has been constructed for a persistent macromolecular. The reasons for the universality of the picture of this transition have been explored (its independence from the microscopic characteristics of the polymer). A method of seeking the parameters of the bead model equivalent to a given persistent chain is indicated. A way of evaluating the axial ratio of the macromolecule (ratio of the persistent length  $l$  to the thickness  $d$  from the experimental data on the coil-globule transition has been found. In cyclohexane and dioctylphthalate  $l/d \approx 2$  has been found for PS. The orientation ordering of portions of the chain in the surface layer of the globule is analyzed numerically. (Author abstract) 15 refs.

**082581 SCATTERING FUNCTION AND THE DYNAMICS OF PHASE SEPARATION IN POLYMER MIXTURES UNDER SHEAR FLOW.** The phenomenological mean-field theory describing concentration fluctuations and spinodal decomposition of binary mixtures of long flexible macromolecules is generalized to mixtures under steady shear flow. This shear flow leads to a partial orientation and stretching of the coils, as well as to an anisotropic deformation of concentration fluctuations. We obtained the collective scattering function describing these concentration fluctuations in the mixture under shear flow. Both the steady-state situation in the one-phase

region and the initial stages of spinodal decomposition for concentrations within of the spinodal curve are considered. (Author abstract) 29 refs.

**082582 DEPENDENCE OF THE GLASS TRANSITION TEMPERATURE OF POLY[N-(n-ALKYLOXY-CARBONYL-METHYL) MALEIMIDES] AND POLY[N-(5-n-ALKYLOXYCARBONYL-n-PENTYL) MALEIMIDES] ON n-ALKYL SIDE-CHAIN LENGTH.** The glass transition temperature has been determined by a refractometric techniques for two homologous series of poly[N-(n-alkyloxycarbonyl-methyl) maleimides] (PEMIS 1) and poly[N-(5-n-alkyloxycarbonyl-n-pentyl) maleimides] (PEMIS 5) with the outer part of the n-alkyl side-chain ranging in length from ethyl to dodecyl for PEMIS 1 and from ethyl to decyl for PEMIS 5 and including only the even members of the series. The glass transition temperature is directly related to the number of methylene groups in the outer part of the n-alkyl side-chain (including terminal methyl) of the repeating unit. A semiempirical equation is presented that affords estimates of  $T_g$  that are in good agreement with the experimental data. (Author abstract) 47 refs.

**082583 INSULATOR-TO-METAL TRANSITION IN POLYANILINE.** A study of the magnetic susceptibility of the emeraldine form of polyaniline shows the presence of a Pauli susceptibility approximately linearly proportional to the degree of protonation in agreement with phase segregation into metallic and nonmetallic phases. A model based upon the transition upon protonation from isolated doubly charged protonated diimine groups to a polaronic metal is suggested, together with the role of localization of polarons at the surface of and within the disordered small metal particles formed. (Author abstract) 34 refs.

Ginder, J.M. (Ohio State Univ, Columbus, OH, USA); Richter, A.F.; MacDiarmid, A.G.; Epstein, A.J. *Solid State Commun* v 63 n 2 Jul 1987 p 97-101.

**082584 INFLUENCE OF THE GLASS TRANSITION ON SOLVENT SELF-DIFFUSION IN AMORPHOUS POLYMERS.** The free-volume theory of diffusion is used to analyze the temperature dependence of solvent self-diffusion coefficients both above and below the glass transition temperature at concentrations removed from the pure polymer limit. The glass transition can have a pronounced effect on the temperature dependence of solvent self-diffusion coefficients at small solvent concentrations, but the theory predicts a decreased effect of the transition on the diffusion process with increasing solvent concentration. (Author abstract) 9 refs.

**082586 PHOTOACOUSTIC STUDY OF PTS (BIS-P-TOLUENE SULFONATE OF 2, 4-HEX-**

**ADIENE-1,6-DIOL) SINGLE CRYSTAL AND ITS THERMAL PROPERTIES.** The photoacoustic signal and phase angle of a single crystal of polybis(p-toluene sulfonate) of 2,4-hexadiene-1,6-diol (PTS) were measured in the temperature range of 175-225 K. The jump of the photoacoustic signal and phase angle, and the presence of a peak in  $C_p/K_s$  (here  $C_p$  and  $K_s$  are the specific heat and thermal conductivity of PTS, respectively) near 200 K can be attributed to the second-order phase transition in PTS. The thermal conductivity of PTS, which is given for the first time, is directly proportional to the temperature in the above temperature range. This anomalous behavior is discussed. (Author abstract) 23 refs.

**082587 IGNITION PHASE TRANSITION OF A POLYMER: CONVECTIVE EXPOSURE.** The ignition of a semi-infinite solid polymer under convective exposure is investigated. A quasi-steady approximation is used for the gas phase and the transient effect is accounted for in the solid phase only. Both surface and gas phase chemical reactions are included simultaneously. The ignition mechanism is studied in terms of the concurrent heat transfer, mass transfer and chemical processes at the surface as well as in the gas phase. The gas phase governing equations are integrated independently from the solid phase energy equation using the Adams-Moulton subroutine. Corrections to the iterative procedure are carried out by establishing a set of perturbation equations and using the Newton-Raphson and least-squares methods. The results indicate that ignition occurs in the heterogeneous mode within a narrow range of low flow velocities and high temperatures. An ignition phase transition point exists, and within a wide range of high flow velocities, ignition switches to the homogeneous mode. (Author abstract) 32 Refs.

**082588 THEORY OF THE PHASE TRANSITION UNDER STRESS IN POLY(BUTYLENE TEREPHTHALATE).** Poly(butylene terephthalate) undergoes a reversible phase transition when subjected to a longitudinal stress. The temperature dependence of the critical stress is examined in terms of a model of nucleation and growth and is related to the temperature dependence of the width in stress of the hysteresis loop. Experimental evidence shows that while contributions to the entropy from changes in phonon frequencies at the transition and internal stresses caused by morphological effects may play some role, they do not appear capable of accounting for the observed temperature dependence of the critical stress. A model of nucleation and growth on the other hand, appears consistent with the observed data in that a predicted relation between the critical stress and the width of the hysteresis loop is obeyed. (Edited author abstract) 8 Refs.

Al-Jishi, Radi (California State Univ, Los Angeles, CA, USA); Taylor, P.L. *Macromolecules* v 21 n 7 Jul 1988 p 2240-2243.

**082589 MULTINUCLEAR SOLID STATE NMR STUDY OF PHASE TRANSITIONS IN POLY[BIS(4-ETHYLPHENOXY)PHOSPHAZENE]** The authors report preliminary results from  $^{13}\text{P}$  and  $^{13}\text{C}$  NMR studies on the phase transitions of poly[bis(4-ethylphenoxy)phosphazene] (PBEP) along with the results of DSC thermal analysis and X-ray diffraction analysis. The temperature dependence of the  $^{31}\text{P}$  MAS/DD spectra of PBEP is presented. At low temperatures, there are three components with different chemical shifts, which correspond to the crystalline, interfacial, and amorphous phases. This assignment has been confirmed by the real time observation of the crystallization process from the mesophase at 75°C. The chemical shift of the crystalline phase is least shielded, that of the amorphous phase is most shielded, and that of the interface is intermediate. A discussion is also presented of the nature of the liquid

crystalline phase in poly(organophosphazenes). 34 Refs.

**082590 PHOTODECOMPOSITION AND CHARACTERISATION OF POLYMERS BY UV-LASER INTERACTION.** Ultraviolet-laser-induced emission from various commercial and additive-free polymers were characterized. The olefinic polymers gave a strong Raman emission line corresponding to the H-C-H stretching vibration ( $2875\text{ cm}^{-1}$ ) along with a broad fluorescence which was common to all the samples. The fluorescence was attributed to the chromophoric impurities inherently present in all the polymers. Quenching of emission under uv irradiation was related to the processes of transformation of the chromophores through excited-state reaction and the formation of links between polymer chains. (Author abstract) 13 refs.

**082591 PHOTOCHEMICAL REARRANGEMENT OF POLYMERIC N-(1-PYRIDINIO) AMIDATES. A NOVEL, AQUEOUS PHOTORESIST SYSTEM.** The application of photochemistry to polymer science is especially interesting when the photochemical alteration of solubility is extremely pronounced. One approach the authors have taken is to look for photochemical isomerization reactions that are accompanied by a large change in polarity. One of the interesting reactions, described in a review article on aminimides (or ammonio-amidates), is the photochemical rearrangement of N-(1-pyridinio) amidates, I, to N-acyldiazepines, II. It occurred to the authors that conventional polymer films, containing pyridinio amidate groups, might exhibit large solubility changes after irradiation. This paper describes the implementation of this chemistry as the basis of a new, interesting type of photoresist. 9 refs.

## Photochromism

**082592 FORMATION OF MOLECULAR H- AND J-STACKS BY THE SPIROPYRAN-MEROCYANINE TRANSFORMATION IN A POLYMER MATRIX.** Kinetic and spectral properties of merocyanine dyes, formed on irradiation of spiropyran dissolved in a polymer matrix, depend on the spiropyran concentration. The observed properties are explained by a model in which the merocyanine molecules form molecular H-stacks. A method for formation of molecular J-stacks in the polymer matrix was also developed. Stabilization of the merocyanine dye in the J-stacks completely prevents the conversion back to spiropyran. (Author abstract) 19 refs.

**082594 SPIROPYRAN-ODONIUM SALT SYSTEM AS A TWO PHOTON RADICAL PHOTOINITIATOR.** A variety of radical photoinitiators sensitive to visible light have been attracting interest with respect to the application of photosensitive resins to laser imaging technology. It has been reported that a photochromic spiroopyran conjugated with a benzophenone moiety acts as a photoinitiator for radical polymerization under simultaneous irradiation with both uv and visible light. Recent work has revealed that some dyes including merocyanines and cyanines are effective radical photoinitiators when coupled with iodonium salts. This prompted the authors to study the efficiency of radical photoinitiation using the ring opened, colored form of a spirobenzopyran which has a cyanine dylike structure. This paper deals with the enhancement of radical photopolymerization initiated with readily available 1,3,3-trimethylindolino-6-nitrospirobenzopyran (SP) combined with diphenyliodonium hexafluorophosphate (DPI) by subsequent exposure of the uv irradiate film to a He-Ne laser beam. 12 refs.

**082595 HOLE TRANSPORT IN POLYMERS OF (N-ETHYLCARBAZOL-3-YL)METHYL ACRYLATE AND METHACRYLATE.** (N-Ethylcarbazol-3-yl)-methyl acrylate and methacrylate were polymerized anionically and radically. Anionically-polymerized polyacrylate using ethylmagnesium chloride-benzalacetophenone as catalyst is an isotactic rich polymer with 85% isotactic dyad. All polymers except anionically polymerized polymethacrylate showed good film forming property. Hole drift mobilities measured by the time-of-flight method at room temperature and at  $5 \times 10^5$  V/cm are in the following order: isotactic polyacrylate ( $1.0 \times 10^{-5}$  cm<sup>2</sup>/V s) > atactic polyacrylate ( $1.8 \times 10^{-6}$  cm<sup>2</sup>/V s) > atactic polymethacrylate ( $1.2 \times 10^{-6}$  cm<sup>2</sup>/V s) at  $5 \times 10^5$  V/cm. These results are discussed in terms of the hopping model between localized sites. (Author abstract) 14 refs.

**082598 PHOTOSENSITIVE POLY(METHACRYLATES) HAVING STYRYLPYRIDINIUM AND STYRYLQUINOLINIUM GROUPS.** Three methods to introduce photodimerizable styrylpyridinium or styrylquinolinium groups to methacrylate polymers are described. Among these, copolymerization of methacrylate monomers with methacrylated styrylpyridine or styrylquinoline offered the most convenient procedure to prepare photosensitive polymers because of the excellent solubility of the polymers having the photofunctional groups in high content. Subsequent treatment with p-toluenesulfonic acid to quaternize the pyridine or quinoline moiety made the polymer highly photosensitive. The polymers having a styrylquinolinium group were found to be sensitive to 488 nm light of an Ar laser, and the sensitivity was about 3 mJ/cm<sup>2</sup> when the content of the photosensitive group was 15 mol %. (Author abstract) 8 refs.

Ichimura, Kunihiro (Research Inst for Polymers & Textiles, Tsukuba, Jpn); Oohara, Noboru. *J Polym Sci Part A* v 25 n 11 Nov 1987 p 3063-3077.

**082599 PHOTOSENSITIVE RESINS CONTAINING p-DIMETHYLAMINO BENZYLIDENE DERIVATIVES AND DIPHENYLIODONIUM SALT AS PHOTOINITIATORS.** A series of p-dimethylaminobenzylidene derivatives was able to sensitize the photodecomposition of diphenyliodonium salt to afford highly photosensitive negative-type resins. When a polymer-bearing methacryloylated group in the side chain was sensitized with a combination of the p-dimethylaminobenzylidene compounds and the iodonium salt, the polymer demonstrated high sensitivity even to 488 nm light emitted from an Argon laser. The same photoinitiator systems were applicable to insolubilize poly(glycidyl methacrylate) through cationic photopolymerization. The storage stability of these types of photoinitiators depends on the structure of the benzylidene compounds; decreasing the basicity of the amino group enhanced the thermal stability. (Author abstract) 9 refs.

**082603 LOW-PRESSURE CO<sub>2</sub> SORPTION IN POLY(VINYL BENZOATE) CONDITIONED TO HIGH-PRESSURE CO<sub>2</sub>.** Sorption of CO<sub>2</sub> in poly(vinyl benzoate) was gravimetrically measured at pressures up to 1 atm. Sorption isotherms were determined above and below the glass transition temperature T<sub>g</sub> from 5 to 85°C. The isotherms were analyzed by the dual-mode sorption model assuming that the plasticizing effect of sorbed CO<sub>2</sub> is negligible at this pressure range. The solubilities and Henry's law dissolution parameters were compared with those obtained by the high-pressure sorption and permeation measurements. Henry's law dissolution parameters were in good agreement with one another. However, the solubilities first determined here were smaller than those determined by the high-pressure sorption experiment at the same temperature. It was clear that the Langmuir capacity of the present specimen was smaller in spite of similar high-pressure CO<sub>2</sub> exposure. Relaxation of the polymer was expected to be one of the reasons. This expectation was confirmed from the observation and analysis of sorption isotherms after two kinds of treatments. (Edited author abstract) 17 refs.

**082605 DIFFERENTIATION BETWEEN CONFORMATIONAL TRANSITIONS OF POLYMERS AND THE TRANSITION OBSERVED NEAR THE THETA CONDITIONS.** The differentiation between the conformational transitions of polymers and the transition observed near the  $\theta$  conditions has been investigated. The conformational transitions are related with side-group effects and vanish under the influence of an appropriate amount of a polar solvent. In the contrary, the transition observed in the vicinity of the  $\theta$  temperature is related with chain-backbone effects. The addition of a polar solvent shifts this transition to a different temperature in accordance with the resulted change of the  $\theta$  temperature of the system. (Author abstract) 21 refs.

**082607 EFFECTS OF FLOW AND THERMODYNAMIC SWELLING ON THE TRANSLATIONAL MOBILITY OF MOLECULES OF MODERATELY RIGID POLYMERS.** The values of the Kuhn segment and the hydrodynamic cross-section are determined for a series of polymer-solvent systems, with due allowance for the effects of flow and volume swelling on the translational mobility of the molecules. The polymer-solvent thermodynamic interaction parameters for the same system are evaluated. Failure to allow for volume effects results in an apparent increase in the equilibrium rigidity and to a decrease in the hydrodynamic cross-section of the molecules. (Author abstract) 18 refs.

**082608 MOLECULAR WEIGHT DEPENDENCE OF INTERFACIAL TENSION OF POLY(ETHYLENE GLYCOLS).** The surface tensions ( $\gamma$ ) of Poly(ethylene glycol) (PEG) are almost independent of molecular weight (M). However its interfacial tension ( $\gamma_{12}$ ) is expected to show some M dependence, because of the different affinities of the repeating unit ( $-\text{CH}_2-\text{CH}_2-\text{O}-$ ) and the end group ( $-\text{OH}$  or  $-\text{CH}_2-\text{CH}_2-\text{OH}$ ) to the contacting liquids. This dependence was proved. (Edited author abstract) 13 refs. In Japanese.

**082610 LASER DESORPTION/FOURIER TRANSFORM MASS SPECTRA OF POLY(PHENYLENE SULFIDE), POLYANILINE, POLY(VINYL PHENOL) POLYPYRENE, AND RELATED OLIGOMERS: EVIDENCE OF CARBON CLUSTERS AND FEASIBILITY OF PHYSICAL DIMENSION MEASUREMENT.** Lasers desorption/Fourier transform mass spectra of poly(phenylene sulfide), polyaniline, poly(vinyl phenol), polypyrrole, poly(p-phenylene), poly(1-methyl-2,5-pyrrolylene), poly(1-phenyl-2,5-pyrrolylene), and poly(2,5-thienylene) are compared. Poly(phenylene sulfide) fragments at C-S bonds during analysis, but rearrangement is minor. Evidence is found for dibenzothio-phenone moieties within the polymer chains. Unambiguous determination of the structure of polyaniline is not possible. Rearrangement appears to accompany chain scission. Completely aromatic polymers do not undergo similar reactions during analysis. Species with more carbons than can be accounted for by an integer multiple of six-membered rings arise from side reactions during dehydrocoupling of aromatic monomers. Carbon clusters, which are observed in the spectra of some aromatic polymers, appear to arise from laser volatilization and multiphoton ionization of large polynuclear components that are formed during synthesis. (Edited author abstract) 66 refs.

**082611 SYNTHESIS, PHYSICAL, AND THERMAL PROPERTIES OF LINEAR POLYDIALKOXYPHOSPHINYL-S-TRIAZINES.** A novel class of linear poly(dialkoxyposphinyl-s-triazines) were prepared by interfacial or solution polycondensation reactions of various diamines such as ethylenediamine, hexamethylenediamine or bis(4-aminocyclohexyl)methane with 2-dialkoxyposphinyl-4, 6-dichloro-s-triazines. The latter were synthesized by reacting cyanuric chloride with an equimolar amount of trialkyl phosphite. The phosphorus-containing polymers were characterized by inherent viscosity measurements as well as by infrared (IR) and proton nuclear magnetic resonance (<sup>1</sup>H-NMR) spectroscopy. The thermal properties of polymers were investigated by differential thermal analysis (DTA) and thermogravimetric analysis (TGA). (Edited author abstract) 22 refs.

**082613 PACKING DENSITY OF THE AMINE-CROSSLINKED STOICHIOMETRIC EPOXY NETWORKS.** The packing densities (Van der Waals volume/molar volume) were determined at 293 K for various epoxide-amine stoichiometric networks. They are noticeably higher than those of linear polymers except strongly hydrogen bonded ones [polyamides, poly(vinyl

alcohol)]. By extrapolation of the dilatometric data it was found that the packing densities at the frontiers of the glassy state (0 K and T<sub>g</sub>) of the epoxy networks are comparable to those of linear polymers having the same theoretical hydrogen bond density (polyamides). However, for a given packing density at 0 K, the packing density at T<sub>g</sub> is higher for a network than for the corresponding linear polymer. (Author abstract) 25 refs.

**082614 POLYMER COMPATIBILITY AND INTERPOLYMER ASSOCIATION IN THE POLY(ACRYLIC ACID)-POLYACRYLAMIDE-WATER TERNARY SYSTEM.** Polyacrylamide and poly(acrylic acid) form a water-insoluble phase when solutions of the two having concentrations that are not too low are mixed. The insoluble complex contains nearly stoichiometric 1:1 ratios of acrylamide and acrylic acid. The phase behavior of the ternary system was studied as a function of the degree of neutralization,  $\alpha$ , of poly(acrylic acid). The complex is not formed when  $\alpha$  is high. The formation of the complex was studied by measurement of pH increases observed when poly(acrylic acid) was titrated with polyacrylamide to infer a degree of linkage,  $\theta$ , between the two polymers. A Hill plot of the data showed that the association was cooperative when the molecular weight was high. (Author abstract) 10 refs.

**082615 ATROPISOMERISM IN POLYMERS. SCREW-SENSE SELECTIVE POLYMERIZATION OF ISOCYANIDES BY INHIBITING THE GROWTH OF ONE ENANTIOMER OF A RACEMIC PAIR OF HELICES.** The authors describe a method for the preparation of a polymer with an excess of either left- or right-handed helices, starting from an achiral isocyanide. To this end, they added a slowly polymerizing optically active isocyanide as comonomer to a rapidly polymerizing achiral isocyanide. CD spectra and optical rotation indicate that the screw sense of the resulting polymer samples is opposite to the one preferred by the homopolymer of the optically active comonomer. A mechanism is proposed according to which the optically active comonomer is preferentially incorporated in one of the two helices formed from the achiral isocyanide, viz. the one that corresponds to its own homopolymer. (Edited author abstract) 46 refs.

Kamer, Paul C.J. (Univ at Utrecht, Utrecht, Neth); Cleij, Marco C.; Nolte, Roeland J.M.; Harada, Tadao; Hezemaans, Alphons M.F.; Drenth, Wiendelt. *J Am Chem Soc* v 110 n 5 March 1988 p 1581-1587.

**082616 NEW TELECHELIC POLYMERS AND SEQUENTIAL COPOLYMERS BY POLYFUNCTIONAL INITIATOR-TRANSFER AGENTS (INIFERS).** The unsaturated aliphatic dichlorides cis and trans Cl(CH<sub>2</sub>)<sub>2</sub>C-CH=CH-C(CH<sub>2</sub>)<sub>2</sub>Cl in conjunction with BCl<sub>3</sub> have been found to be excellent binifers and yield tert.-Cl capped polyisobutylenes PIB in CH<sub>2</sub>Cl at -30°C. Intramolecular cyclization is absent and terminal chlorine functionality is F<sub>n</sub>=2.0±0.1. The normalized inifer constants have been determined for the first and second allylic chlorines in the cis isomer. The inequality of the chlorines have been analyzed. The cis and trans isomers have identical relative termination constants. The structure of the PIBs obtained has been analyzed by a variety of techniques. (Edited author abstract) 18 refs.

Mah, Soukhil (Univ of Akron, Akron, OH, USA); Faust, Rudolf; Zsuga, Miklos; Kennedy, Joseph P. *Polym Bull (Berlin)* v 18 n 5 Nov 1987 p 433-440.

**082617 INSTABILITY OF POLARONS AND BIPOLARONS IN CONDUCTING POLYMERS AT VARIOUS 3-d ORDERING TYPES.** Interchain electron hopping  $t_1$  in conducting polymers with the small confinement parameter  $\gamma$  leads to the antiferromagnetic (AF) 3-d ordering of the dimerization pattern only at  $2t_1^2 > \gamma\Delta^2$  (2d being the Peierls gap), otherwise the ferromagnetic (AA) one occurs. Polarons (Ps,  $v=1$ ) and bipolarons (BPs,  $v=2$ ) stability areas:  $t_1/\Delta < t_c(v, \gamma)$  are found in the phase plane  $-t_1$  vs  $\gamma$  with critical  $t_c$  being larger in the AB phase and for BPs. At the AA-AB transition interface, —deconfinement— of kink-solitons is possible. Photogeneration of Ps and BPs may proceed via metastable free states separated by the self-trapping barriers (STBs) which are also different in AA and AB (in the latter STBs exist even in 2-d systems) and are lower for BPs. (Author abstract) 24 refs.

**082618 INTERFACIAL TENSION OF POLY(PROPYLENE GLYCOLS) AND THEIR BLOCK COPOLYMERS WITH POLY(ETHYLENE GLYCOL)S AGAINST POLYETHYLENE AND POLY(VINYL ACETATE).** Interfacial tensions ( $\gamma_{12}$ ) were measured at various temperatures for poly(propylene glycol)s (PPG) with different molecular weights (M) and copolymers of propylene oxide (PO) and ethylene oxide (EO) in contact with polyethylene (PE) and poly(vinyl acetate) (PVAc).  $\gamma_{12}$  of PPG/PE systems did not depend on M, while for PPG/PVAc systems it increased with M. The linear relationship of  $\gamma_{12}$  to  $1/M$  was found.  $\gamma_{12}$  of copolymer/PE systems slightly increased with increasing mole fraction of EO ( $X_2$ ), while  $\gamma_{12}$  of copolymer/PVAc systems decreased rapidly with  $X_2$ , because of selective adsorption of EO block onto the polar PVAc interface. Contact angles ( $\theta$ ) of copolymers were also measured on polypropylene (PP), paraffine and polytetrafluoroethylene (PTFE). (Edited author abstract) In Japanese. 4 refs.

**082619 PHOTOELASTICALLY ACTIVE POLYMERS WITH DIFFERENT MODULI PREPARED FROM BIS(CYCLOPENTADIENYL) OLIGOMERS FOR USE IN PHOTOELASTIC MODEL ANALYSIS.** Crosslinked, photoelastically active polymers having different transition temperatures and different moduli in the rubberlike state have been prepared by Diels-Alder polyaddition from bis(cyclopentadienyl) oligomers and diallyl esters of various dicarboxylic acids. The polymers are intended for use as materials with controlled Young's modulus in photoelastic model analysis. The authors conclude that the obtained results demonstrate the possibility to prepare crosslinked polymeric materials with controlled values of  $T_g$ ,  $E$ , and  $C_p$  from bis(cyclopentadienyl) oligomers by varying systematically the composition and structure of the copolymers. For almost any temperature interval of 20 to 30°C width, materials can be selected with a given ratio of moduli (up to about 10:1); this broadens the scope of problems that can be solved by photoelastic model analysis. 16 refs.

**082621 PROPERTIES OF POLYQUINOLINES AND OF FIBRES BASED ON THEM.** The properties of PQ (Polyquinolines) of various chemical structures and the conditions for preparing fibers from them are examined. Synthesis of the PQ was carried out in a mixture of m-cresol and phosphorus pentoxide at 140°C by polycondensation of 3,3'-dibenzoyl-4,4'-diaminodiphenyl ether with a series of diacetyl compounds. The polymers were isolated from the polycondensation solutions by precipitation into a mixture of ethanol and triethylamine; they were extracted with boiling ethanol, and were dried to constant weight under vacuum. Experimental data indicate that it is advisable to use this dry-spinning method to obtain fibers from polyquinolines which have satisfactory physicochemical properties. 5 refs.

**082622 QUANTITATIVE DESCRIPTION OF SMALL MOLECULE BINDING TO ABIOTIC POLYMERS.** The variation of equilibrium constants for the binding of small molecules to abiotic polymers as a function of structure is quantitatively described by the intermolecular force (IMF) equation and relationships derived from it. Structural variations in both the small molecules and in the polymers were studied. The data were taken from the literature. The results obtained suggest that the IMF equation may be generally useful for modeling the effect of structural variation on polymer properties which depend on the difference in intermolecular forces between initial and final states. They also provide model for nonspecific binding to biopolymers. (Author abstract) 14 refs.

**082624 <sup>13</sup>C-NMR SEQUENCE DETERMINATION FOR MULTICOMPONENT POLYMER MIXTURES.** A general treatment is developed for the <sup>13</sup>C-NMR analysis of polymers which contain several components. Reaction probability models and computer optimization techniques are used to resolve the NMR spectral data into separate components. The use of generalized multistate statistical models is introduced and is found to be very suitable for such systems. The computations are simplified by means of computer programs. The need for, and the relevance of, this approach are illustrated by the tacticity problems in polybutylene and polypropylene where two-state and three-state models are used, and copolymer triad sequence analysis for several olefin and acrylic copolymers where two-state models are needed. Three copolymer examples are given: propylene/butylene, ethylene/propylene, and acrylamide/acrylate. (Author abstract) 40 refs.

Cheng, H.N. (Hercules Inc, Wilmington, DE, USA). *J Appl Polym Sci* v 35 n 6 May 5 1988 p 1639-1650.

**082625 SHORT POLYMER CHAIN STATISTICS AND THE RELATIONSHIP TO END TO END ELECTRONIC EXCITATION TRANSPORT: RANDOM WALKS WITH VARIABLE STEP LENGTHS.** The problem of the distribution of distances between the ends of a polymer chain for short chains (a small number

of statistical segments) is considered. A formalism developed by Rayleigh is utilized to calculate the exact end to end distribution functions for random walks with a small number of steps and variable step lengths. In particular, distribution functions for walks in which the first and last step differ in length from the intervening steps are obtained. These are used as models for low molecular weight polymers in which the first and last statistical segments are different from internal segments because of chain end effects or chromophores attached to the chain termini. The results are used to calculate the ensemble averaged time dependence of end to end electronic excitation transport. (Edited author abstract) 17 refs.

**082627 MEMORY EFFECTS IN POLYMERS. I. ORIENTATIONAL MEMORY IN THE MOLTEN STATE; ITS RELATIONSHIP TO POLYMER STRUCTURE AND INFLUENCE ON RECRYSTALLIZATION RATE AND MORPHOLOGY.** The influence of polymer structure on the orientational memory in the molten state has been studied by observing the crystallization behavior of the molten polymer through differential scanning calorimetry. It is shown that polymers with strong intermolecular forces (e.g., H-bonding) retain the orientation memory even at temperatures above their equilibrium melting temperatures. The retained orientation memory of the polymer melt is shown to influence its recrystallization rate and the morphology. Some of the polymers covered include nylon polymers, polyethylenes, and polyethylene terephthalate. 3 refs.

Khanna, Y.P. (Allied-Signal Inc, Morristown, NJ, USA); Reimschuessel, A.C. *J Appl Polym Sci* v 35 n 8 Jun 1988 p 2259-2268.

**082628 PROPERTIES OF POLYMERS BASED ON MODIFIED POLYAMIDES.** Results are reported of the research in the mechanisms of the chemical modification of polyamides by N,N'-maleimide and the effects of the chemical structure and content of N,N'-bis-maleimide on the properties of the materials produced. It was found that the incorporation of 0.5 mass% of BMI bis-maleimides (the relative viscosity of the original sample being 2.3) in the polyamide results in the relative viscosity of the soluble fraction of the sample rising to 2.8 and in the emergence of a gel fraction amounting to 3 mass%. Increasing the quantity of BMI (I) to 5 mass% results in the relative viscosity of the soluble fraction rising to 3.2 and in the gel fraction rising to 29 mass%. 5 refs.

Volzoin, A.I. (Acad of Sciences of the Byelorussian SSR, USSR); Sointsev, A.P.; Mironovich, L.L.; Yurkevich, O.R. *J Appl Chem USSR* v 60 n 7 pt 2 Jul 1987 p 1510-1512.

**082629 MECHANICAL SELF-SIMILARITY OF POLYMERS DURING CHEMICAL GELATION.** Network polymers near their gel point exhibit self-similar mechanical behavior, as expressed by power law relaxations. The range of self-similarity is defined by two limiting length scales. The upper limit is the correlation length, defined by the linear size of the typical cluster, and a lower limit, roughly given by the size of one preformed linear chain, i.e., the mean distance between crosslinks. The correlation length increases with the approach to the gel point, and diverges at the critical extent of reaction, i.e., the gel point where the infinite cluster is formed. Above the gel point, it decreases again with further crosslinking. Dynamic mechanical measurements of the complex modulus at the gel point show a power law in the frequency dependence over the entire frequency range, monitoring self-similarity. Swelling effects reduce the fractal dimension of the percolation cluster from 2.5 to 2. (Edited author abstract). 30 Refs.

**082630 UNIFIED STUDY OF THE DIFFERENT PHYSICAL PROPERTIES OF AMORPHOUS POLYMERS.** A phenomenological model is proposed which tries to explain the mechanical, optical and thermal properties (both thermal conductivity and expansivity) of amorphous polymers. The model has similarities with the composite model, proposed by the present authors, which has proved to be successful in interpreting the different physical properties of semicrystalline polymers. The present model considers the bulk form of the polymer as an aggregate of microscopic units possessing intrinsic physical properties. On drawing, the development of anisotropy in different physical properties is supposed to be due to the development of preferred orientation of these units. The development of the preferred orientation has been estimated directly from birefringence data. The agreement between the calculated and experimental values of the elastic modulus, thermal conductivity and thermal expansivity of PVC, PMMA and PS is found to be reasonably good. (Edited author abstract). 37 Refs.

**082631 PREDICTION OF PHYSICAL PROPERTIES OF POLYMERS FROM ELECTRICAL FLUCTUATIONS MEASURED OVER A BROAD TEMPERATURE INTERVAL.** The relationship between thermal expansion and electrical fluctuations in polymers is discussed. The variation of fluctuation voltage in the region of transition to the liquid state and at the onset of the process of chemical relaxation correlates well with specific features of the dilatometric curve. Values of physical characteristics obtained by means of the proposed method for poly(vinyl chloride) and a nitrile rubber vulcanizate are in good agreement with results of traditional methods. (Author abstract). 15 Refs.

Zelenev, Yu. V. (F.E. Dzerzhinskii Military Acad of Aviation Engineering, Tambov, USSR); Ivanovskii, V.A. *Polym Sci USSR* v 29 n 4 1987 p 898-904.

**082632 GROUP CONTRIBUTION ANALYSIS OF THE DAMPING BEHAVIOR OF HOMOPOLYMERS, STATISTICAL COPOLYMERS, AND INTERPENETRATING POLYMER NETWORKS BASED ON ACRYLIC, VINYL, AND STYRENIC MONOMERS.** The integral of loss modulus versus temperature plots in the vicinity of the glass transition temperature (loss area, LA) was characterized for various homopolymers, statistical copolymers, and interpenetrating polymer networks (IPNs), based on acrylics, vinyls, and styrenic monomers. The quantity LA was found to be a molecular characteristic, governed by the structure of the molecular chains. The LA of both IPNs and statistical copolymers obeys an additive relation of the component polymers. A group contribution analysis for LA was developed in which each moiety contributes a specific value to LA. A table derived via this group-contribution analysis permits the prediction of LA values. The results show that

backbone motions and the moieties attached directly to the backbone contribute the most to the damping peak, and that long side chains act as diluents. (Author abstract). 49 Refs.

## Plasticity

**082633 PLASTIC DILATATION DUE TO COMPRESSION IN POLYMER SOLIDS.** For the purpose of studying a constitutive equation and inferring a yield mechanism in polymer solids, dilatational strain due to inelastic deformation must be investigated. In general, it is assumed in the empirical constitutive laws of metals that volume expansion does not occur due to plastic deformation. This may be proved to be true since the plastic deformation of metals is induced by the motions of dislocations subjected to shear stresses. Yielding in polymer solids, however, is strongly influenced not only by the second invariant of deviatoric stress, but also the first stress invariant. The yield condition in polymers is known to be well explained by a modified Mises theory. 5 refs.

## Porosity

**082634 SEPABEADS FP SERIES: NEW HIGHLY POROUS HYDROPHILIC SUPPORTS FOR PROTEIN SEPARATION.** The use of the new chromatographic packing material, Sepabeads FP series, has been examined in industrial-scale separations. They showed sufficient stability and have a highly porous hydrophilic nature which makes them suitable for the purification of biopolymers such as proteins. It was found that the protein adsorption capacity strongly depends on the porosity, i.e., mean pore radius, of the packing as well as on the type of attached functional groups. Using Sepabeads FP series, industrial-scale separations of biopolymers in various chromatographic modes have become practical. Basic properties of Sepabeads FP series and some applications to the separation of proteins are briefly described. (Author abstract) 7 refs.

**082635 NATURE AND STRUCTURE OF POROUS ORGANIC POLYMERS.** Macroporous organic polymers of both aliphatic and aromatic structures can be prepared with various internal properties and surface selectivities. Specific surface areas (by BET) of 0.1 to 1000 m<sup>2</sup>/g can be achieved with concomitant ranges in pore diameters from less than 20 Å to about 500,000 Å. The method of synthesis provides for the great latitude within the internal structure; and the surface selectivity is regulated by the nature of the monomer compositions, or post-reaction of the polymers, or both. The impact of pores and channels within a polymer is examined. Following a scrutiny of the impact of pores and channels within a polymer, guidelines are presented to allow a best selection of porous polymers. (Edited author abstract)

**082636 FOLOSIREA POLIACRILAMIDELOR HIDROLIZATE IN APE DE ZACAMINT CU IONI DIVALENTI.** [Utilization of Hydrolyzed Polyacrylic

Amides in Deposit Waters with Divalent Ions]. The main parameters conditioning the stability of the hydrolyzed polyacrylic amides in the injection and deposit waters containing divalent ions are presented. The viscosity behavior of the polymers and their precipitation or insolubilization tendency, under field conditions, can be predicted by taking into account the whole ionic load of the solution, and not from the divalent ion contents only. In the vicinity of the solubility curve the decreased of the Huggins' constant indicate the reaching of quasi  $\theta$  conditions. (Authors abstract) In Romanian. 9 refs.

## Pressure Effects

**082637 TENSILE PROPERTIES OF POLYVINYLIDENE FLUORIDE (PVDF) UNDER HYDROSTATIC PRESSURE.** For polymers, in general, the effects of hydrostatic pressure on mechanical properties are considerably different from those for metals: the yield stress and elongation at fracture have been reported to change with hydrostatic pressure to various degrees, depending on temperature and strain rate. Results of tension tests on PVDF under pressures up to 392 MPa, at temperatures up to 90°C, and with strain rates up to 1 s<sup>-1</sup> are reported in this paper. As pressure increased, the yield stress increased and the elongation decreased; as temperature was raised the yield stress became lower and the elongation higher. The brittle-to-ductile transition was observed near 30 MPa. Empirical formulas for the stress-strain curves were obtained in the post yield region. The glass-transition temperature T<sub>g</sub> of PVDF was found to be -35°C. When the pressure was raised from 300 to 400 MPa, T<sub>g</sub> shifted to 35°C. (Author abstract) 5 refs. In Japanese.

**082638 POLYMER PROCESSING: AN OVERVIEW.** Polymer processing is discussed in terms of mechanisms, equipment, and transport and reaction phenomena. The purpose of this article is to familiarize chemical engineers with polymer processing by noting both the common roots of the transport and reaction phenomena involved and the differences in mechanisms, and therefore the equipment used, by which the corresponding processes are carried out in the two fields. A discussion is presented of: the handling of particulate solids; melting, softening and solidification of polymers; pressurization and pumping; mixing; and, devolatilization and reactive processing. 33 refs.

**082639 POWDER PROCESSING OF IRON-FILLED UHMWPE.** An alternative to compression molding is described. When iron filler is incorporated, rapid induction heating and consolidation result - cutting composite processing time from hours to a matter of minutes. Experimentation involved the use of UHMWPE from Hercules Inc. (Hi Fax 1900) with an average particle size of 330  $\mu$  and pure iron from Haeganaes Corp. (grade MH-100) with particle size <44  $\mu$  were blended together

in a V-mixer for 10 to 12 hours. The iron particles, being finer, adhered well to the bigger polymer particle surfaces, forming a metallic coating. The polymer particles were coated completely and uniformly, and compacts made from the coated particles resulted in a segregated distribution of the metal particles within the specimen (referred to as 'segregated Fe network'). 8 refs.

**082640 CRITICAL ASPECTS OF INDUSTRIAL AND ACADEMIC COLLABORATION.** It is not enough to have shown that there is a broad and exciting range of potential applications of a new idea; even where the process route has been established and the product proved in exhaustive trials, the innovator still has a formidable task ahead. The introduction of strong polymeric grid materials for long-term applications in civil engineering and general construction provides a typical example of the hard road that must be travelled to reach success. A case history demonstrates some of the ways in which the difficulties can be overcome by a major cooperation between a British company and the research capabilities of five British universities. **082642 ANALYSIS OF THE ROLE OF STRIPPING AGENTS IN POLYMER DEVOLATILIZATION.** A comprehensive model has been developed to analyze the process of polymer melt devolatilization in the presence of a stripping agent, which performs the function of enhancing the molecular diffusion of the desorbing monomer and reducing the interfacial concentration. The problem leads to a coupled set of non-linear partial differential equations with time dependent boundary conditions. This problem has not been solved in the literature so far. The model enables the prediction of the influence of diffusivity ratios, relative volatility, hydrodynamic conditions, etc. on the devolatilizer performance and provides useful guidelines for the selection of a suitable stripping agent. The strategy developed in this work can be also used for related problems of multicomponent desorption in other systems. (Author abstract) 18 refs.

**082643 PROCESS POLYMERS WITH SUPERCRITICAL FLUIDS.** Examples are presented that demonstrate the effectiveness of SCFs (Supercritical Fluids) for purification and fractionation of multicomponent polymer mixtures. This makes possible production of high-purity materials with much more precisely controlled physical-chemical properties. SCFs offer considerable potential for other types of polymer processing. For example, R.C. Peterson et al. have described the use of rapid decompression of SCF polymer solutions for preparation of finely divided polymer powders. S. Kumar et al. have also reported the use of SCFs as precipitation polymerization media where the degree of polymerization can be controlled by varying the SCF density. 24 refs.

**082644 CONTINUOUS PREPARATIVE METHOD OF RELATIVELY LARGE AND UNIFORM POLYMER BEADS AND THEIR APPLICATION TO IMMOBILIZATION OF UREASE.** An apparatus for continuous preparative method of polymer beads was investigated. Monomer droplets formed in glycerol were continuously introduced to a rotating glass tube which was filled with warmed glycerol and polymerized. Polymer beads of around 4 mm diameter were obtained. As an application of the polymer beads, urease was immobilized on the beads and their properties were evaluated. Macroreticular type of beads prepared with a mixture of maleic anhydride, styrene, and divinylbenzene showed the highest enzymatic activity among the beads tested, and the urease immobilized beads could be successfully applied for determination of blood urea nitrogen in human sera. (Author abstract) 6 refs.

**082645 SURFACE PLASMON STUDY OF ELECTROCHEMICALLY PREPARED POLYMERS: POLYAZULENE.** The work reported shows that by using a modified gold working electrode, the surface plasmon technique can successfully be used to obtain information on the optical constants and the film thickness of electropolymerized films. Polyazulene films deposited at three different surface charge densities are investigated in the oxidized and corresponding reduced forms. The authors results shows that the refractive index, and hence the dielectric constant at 632 nm, is complex, the imaginary part being larger for the oxidized form compared to that for the corresponding reduced form. **082646 AMPHIPHILIC NETWORKS. I. NETWORK SYNTHESIS BY COPOLYMERIZATION OF METHACRYLOYL-CAPPED POLYISOBUTYLENE WITH 2-(DIMETHYLAMINO)ETHYL METHACRYLATE AND CHARACTERIZATION OF THE NETWORKS.** New amphiphilic networks have been synthesized by free-radical copolymerization of hydrophobic methacryloyl-capped polyisobutylenes (MA-PIB-MA) with hydrophilic 2-(dimethylamino)ethyl methacrylate. Two MA-PIB-MA have been prepared with  $M_n = 4920$  and 10,200, and two series of networks were prepared with MA-PIB-MA contents between 48 and 71.5%. Variation of the molecular weight of MA-PIB-MA and its concentration in the network allows for a wide range of mechanical properties and swellability in hydrophilic and hydrophobic solvents. Differential scanning calorimetry shows the existence of two glass transitions in these networks and thus indicates a phase-separated domain structure. (Edited author abstract). 23 Refs.

**082647 EFFECT OF HYDROGEN BONDS ON THE SOLID PHASE CYCLODEHYDRATION OF POLYAMIC ACIDS.** By X-ray structural analysis of the complexes of pyromellitimide acid with amide solvents it was found that the character of the system of hydrogen bonds and the structure of the solvates depend on the nature of the amide solvent. It was shown that in the case of polyamic acid solvates, the hydrogen bonds formed in the solid polyamic acid films can be studied by mass-spectrometric thermal analysis; from the obtained data, the mechanism may be determined by the function of additives catalyzing the solid phase cyclodehydration of polyamic acids. (Author abstract). 10 Refs.

**082649 PRODUCTION OF WATER-SOLUBLE POWDERED SURFACE-ACTIVE POLYMERS BASED ON STYROMAL.** The purpose of this work is to produce water-soluble powdered polymers based on styrene-maleic anhydride copolymer (Styromal) with a definite ratio of hydrophobic and hydrophilic groups and having surface activity. Investigations showed that the polymers can be obtained in the form of fine powders only at certain ratios of hydrophobic to hydrophilic groups in the macromolecular chains. Decrease of the ester-group content also leads to weakening of surface activity of the polymers. Thus, by regulating the ratio of hydrophilic and hydrophobic groups in the macromolecular chains of the synthesized polymers, it is possible to confer surface activity on them and to obtain them in the form of fine powders, convenient to use and making it possible to extend the range of available surface-active polymers. 4 refs.

**082650 HIGH PURITY FLUOROPOLYMER MATERIALS: TRACE ELEMENT CONTENT AND LEACHING.** Many problems in analytical chemistry are shared by the high purity crystal growth community since both are greatly concerned with the effects of impurities either upon an analysis or upon a device. Fluoropolymers are widely used today in applications where inertness or high purity or both are needed. The behavior of these polymers in high purity solvent systems has been investigated by several analytical techniques. Both the resin from which finished parts are made as well as blow molded bottles have been evaluated to determine cationic impurities in both the resin and in leachates. (Author abstract) 7 refs.

**082651 POLYMER PYROLYSIS: A RESOLUTION OF ANOMALIES IN KINETIC SCHEMES FOR THE RATE OF EVOLUTION OF VOLATILE PRODUCTS.** Kinetic schemes proposed by three groups of workers for polymer pyrolysis have been critically examined, in order to resolve apparent anomalies, especially in the way in which the overall first-order rate constant for volatile evolution by depropagation mechanisms, involving different modes of initiation and termination, have been interpreted. These schemes lead to identical expressions for the initial rate of evolution of a volatile product, provided the symbols are defined specially according to the conventions chosen. These expressions are to be recommended for studies of this kind. (Edited author abstract) 11 refs.

**082652 DETERMINING TEMPERATURE LIMITS FOR POLYMER PYROLYSIS BY MASS SPECTROMETRY.** It is important to determine the temperatures representing the start, peak and end of decomposition in research on polymer stability, as well as the mass loss and the products. These temperatures enable one to forecast working conditions and to some extent facilitate determining destruction mechanisms. These temperatures have been determined for vinyl and allyl copolymers made by free-radical polymerization with various monomer ratios at 75°C in the presence of 0.001 mole of benzoyl peroxide per mole; the specimens were heated in a device coupled to the valve unit in an MKh-1320 mass spectrometer. 4 refs.

**082654 SONOLYSIS OF POLYMERS IN AQUEOUS SOLUTION. NEW OBSERVATIONS ON PYROLYSIS AND MECHANICAL DEGRADATION.** Aqueous solutions of DNAM pectin, poly(acrylamide), poly(vinyl alcohol), poly(vinylpyrrolidone), poly(methacrylic acid), and poly(ethylene glycol) were sonicated under argon and the yields of CO and H<sub>2</sub>O<sub>2</sub> determined. The CO yield is a measure of the pyrolysis of the polymers. DNA is least sensitive toward thermal decomposition, while poly(ethylene glycol) decomposes most rapidly. The H<sub>2</sub>O<sub>2</sub> yield is most strongly decreased by polymers producing the most CO. These polymers also decrease the surface tension of water the strongest. It is concluded that pyrolysis and OH radical scavenging require the accumulation of polymer molecules in the interfacial region around the cavitation bubbles. The mechanical degradation of poly(acrylamide) under various gases (He, Ar, H<sub>2</sub>, CH<sub>4</sub>, C<sub>2</sub>H<sub>4</sub>, CO<sub>2</sub>, N<sub>2</sub>O, air) was also studied. (Edited author abstract) 12 refs.

**082655 CHARACTERIZATION OF SOME PYROLYSED POLYCARBOSILANES BY TRANSMISSION ELECTRON MICROSCOPY.** Four different polymers were pyrolyzed up to 1000°C. The techniques of transmission electron microscopy (TEM) use one of all the

scattered beams emitted by the specimen, selected by a suitable objective aperture displaced relative to the selected area electron diffraction (SAD) pattern. The regions emitting a given beam or portion of a diffraction ring appear in the image as bright domains in a dark field. The various radial positions of the aperture used are indicated. In position 1 turbostratic carbons and various forms of silica can be imaged in DF; SiC is excluded. In position 2, a crystalline SiC 111 DF image is formed, superimposed to a weak carbon 10 DF image. In position 3, only SiC crystals can be imaged. If the material is amorphous, small and faintly bright dots appear for any aperture centering and any focusing value. They correspond to the statistical distribution of couples of atoms within the specimen. 11 Refs.

**082656 POLYMER PYROLYSIS MECHANISMS: EXPERIMENTAL APPROACHES FOR INVESTIGATING THEM.** Choice of pyrolysis conditions for any particular investigation is determined by whether the objective is to assess the thermal behavior of the polymer for a particular application or whether the molecular degradation mechanism is sought. In this connection the effects of nature of the sample, its size, and the heating procedure are discussed. Choosing experimental methods of investigating the degradation depends on which categories of pyrolysis behavior occur; different techniques are required for examining insoluble residues, soluble residues, and evolved volatiles. Processes producing volatiles can be studied with greatest sensitivity, especially by pyrolysis-gas-liquid chromatography. A sequence of experimental approaches is suggested; the target of this is to obtain the most detailed interpretation of the pyrolysis mechanism. (Edited author abstract) 29 refs.

**082658 POSITRON ANNIHILATION IN CORROSION PROTECTIVE POLYMERIC COATINGS. II.** Positron annihilation was studied in four commercial polymeric coatings on iron. Positron lifetime measurements were performed before and after exposure of the coatings to boiling water for 1 h. A correlation was observed between the effect of water exposure on the lifetime spectra and the protective properties of the coatings when exposed to 0.1M sulfuric acid at 60°C for 1010 h. The coatings that provided good corrosion protection in the acid showed minor changes in the positron lifetime spectra upon exposure to water. The spectra of coatings that showed poor corrosion protection, on the other hand, exhibited considerable changes in the

positron lifetime spectra upon exposure to water. (Author abstract) 6 Refs.

**082659 EFFECTS OF RADIATION ON POLYMERS.** The present paper is a brief overview of aspects of the damaging effects of radiation on nuclear plant components manufactured from organic polymers. The paper briefly mentions some general nuclear plant applications of polymers, describes how the properties of polymers are affected by radiation, outlines some of the basic mechanisms which cause these effects, and explains how other environmental parameters, such as temperature, the presence of oxygen or other reactive chemicals, and the rate at which materials are irradiated, interact. Finally, procedures which are being developed to predict the behaviour in the long term from short term accelerated tests are outlined. (Author abstract) 17 refs.

**082660 SEMIDYNAMIC STUDY OF POLYMER SURFACE MORPHOLOGY DEVELOPMENT IN KAPTON-H™ SPUTTER ETCHED BY 6 keV XENON ATOMS.** A semidynamic study of the surface morphology development on 6 keV Xenon atom bombarded polyimide (Kapton-H™) is presented and discussed in light of present models of polymer sputtering and material surface morphology development. Using a series of particle bombardment-gold coating-SEM investigation-gold layer stripping cycles, the whole process of the surface morphology development can be studied in a greater detail. Kapton-H is extremely resistive to particle bombardment. Under high fluence particle bombardment, the surface morphology development proceeds from uniform rows of submicron protrusions to flat-top columns which later disintegrate into long thin fiberlike structures. The average sputtering yield of Kapton-H is about 30 amu/atom (i.e., 0.08 [—C<sub>22</sub>H<sub>10</sub>N<sub>2</sub>O<sub>5</sub>—] monomer units/atom). This value is very low when compared to other polymer materials. (Author abstract) 50 refs.

**082661 RELAXATION OF IMPURITY MOLECULES IN NETWORK POLYMER SYSTEMS BY THE ACTION OF LIGHT.** The possibility was discovered of changing the photochemical activity of impurity molecules in network polymer systems under conditions in which the photon absorbing molecule does not undergo a photochemical reaction. It was found that the photooxidation of anthracene was a photochemical action of light on the state of impurity molecules in the polymer matrix as the result of removal of one of the process components, namely, molecular oxygen. The present work was undertaken in order to determine the influence of temperature and the degree of crosslinking of the polymer systems on the change in the photochemical activity during such treatment. 10 refs.

**082662 SOFT X-RAY IRRADIATION EFFECTS IN POLYMER FILMS.** Monochromatic synchrotron radiation (250 eV < hv < 350 eV) has been used to study the core level electronic excitation processes in solid polymer films of PE, PB, PS and PMMA. The electron yield spectra are closely related to the absorption spectra of the polymer

surface and reveal characteristic core to valence (Cl $\rightarrow\pi^*$ ) and core to Rydberg (Cl $\rightarrow$ R) transitions. These excitations, however, do not produce significant bond rupture and ion desorption contrary to excitations induced by photons of energy  $\geq 290$  eV. For those energies a significant ion yield is obtained. Possible excitation mechanisms are discussed in detail. (Author abstract) 17 refs.

**082663 INVESTIGATIONS ON ENHANCEMENT IN TRACK REVELATION SENSITIVITY OF ALLYL DIGLYCOL CARBONATE (CR-39) DUE TO LASER TREATMENT.** It is shown that for 6 MeV  $\alpha$ -particles, the track revelation sensitivity is higher in the polymer of allyl diglycol carbonate (CR-39) treated with a CO $_2$  laser beam at 25 J/cm $^2$ . With increasing etching time the sensitivity of the laser treated CR-39 increases relative to that of the untreated polymer and for an etching time of about 10 h it becomes twice that of the untreated polymer. The bulk etch rate of about 200  $\mu$ m/h has been estimated at the surface of the laser treated CR-39 and it decreases very rapidly with the time of etching. The track etch rate is also found to be very large in the treated CR-39 and it decreases in the laser affected region as the etching progresses. At the same depth in the polymer sheet, sensitivity of the treated CR-39 is only slightly larger than that of the untreated polymer. Laser induced structural transformation explains most of the observed effects. Laser treatment is shown to increase the sensitivity without reducing the resolution of the polymeric track detector. (Author abstract) 24 refs.

**082664 ELECTRON BEAM EFFECTS ON POLYMERS.** Numerous advances have been made in the understanding and implementation of electron beam (E-beam) technology in the areas of resist materials, coatings, adhesives, films, etc. Yet for today's E-beam practitioner, or those contemplating entering the field, an appreciation of the basic interactions of electron beam radiation with polymeric materials is useful. This article presents an overview of the chemical and physical changes which occur in polymers as a result of electron beam irradiation. 15 refs.

Sidney, LuAnn (3M). *Radiat Curing* v 14 n 3 Aug 1987 p 20, 22-23.

**082665 KINETICS OF THE RELAXATION OF THE SPACE-CHARGE FIELD IN POLYMER DIELECTRICS IRRADIATED WITH GAMMA RAYS.** Research on the relaxation kinetics of the space charge induced by ionizing radiation in dielectrics is of interest for practical applications related to radiation stability, the development of stable high-frequency materials and of materials of electronic and electrotechnical installations operated in fields of ionizing radiation. The details of their relaxation of the electric field of the space charge generated by gamma radiation in a thick plane-parallel dielectric plate has been insufficiently studied until a short time ago. The authors report in the present paper on a solution to the problem of nonisothermal relaxation of the electric field in thick plane-parallel dielectric plates which had been exposed to a gamma-radiation pulse, when a large temperature gradient was present over the sample thickness after the irradiation had ended. 7 refs.

**082666 INTERACTION OF ENERGETIC HEAVY IONS WITH PROBLEMS.** The chemical and physical modifications of linear polymers induced by energetic heavy ions have been compared to those obtained with other electronic excitations. The observed final chemical states are quantitatively the same as those obtained with

X-rays,  $\gamma$ -rays, though a better control of the evolution of the structure of the polymer seems to be achieved by adjusting the experimental conditions (Z, dE/dX, dose rate...). For a given polymer, it is still difficult to predict which modifications will result from the heavy ion irradiation, because of the complex interaction between ions,  $\delta$ -rays and polymers. The desorption of a polar and asymmetric molecule triggers the reorganization of the modified polymer by giving multiple conjugated bonds (allenes, dienes, cycles). On the other hand, the stimulated desorption of a symmetric gas molecule (H $_2$ , F $_2$ , Cl $_2$ ...) will generally lead to non conjugated compounds. Moreover, the nature of the irradiation atmosphere may change the evolution of the irradiated polymers. 39 refs.

**082667 KINETICS AND MECHANISMS OF FREE RADICAL DECAY REACTIONS IN IRRADIATED SOLIDS.** A new second order kinetic equation is given which takes into account the fraction of free radicals which cannot react in solids at the observation temperature. This corresponds to the situation when solids irradiated at liquid nitrogen temperature are then heated to a temperature where only some of the free radicals disappear by recombination. This equation is applied to data for isotactic polypropylene, polybutadiene, linear low density polyethylene, etc. (Author abstract) 7 refs.

**082668 ESR APPLICATION TO RADIATION CHEMISTRY OF POLYMERS.** Important results obtained in our group in the field of ESR application to the study of irradiated polymers are summarized. They are an analysis of the decay reaction of free radicals, the spur-like trapping of the free radicals and related discussions. A diffusion-controlled bimolecular reaction scheme was a good way of analyzing data of the decay reaction. The power saturation phenomenon of the ESR spectra of free radicals showed the spur-like trapping of free radicals in irradiated polyethylene. The phenomenon of spur-like trapping was quite consistent with an interpretation of the decay reaction of free radicals. (Edited author abstract) 20 refs.

**082669 MICROWAVE ENHANCED DIFFUSION IN POLYMERIC MATERIALS.** A process is described using microwave radiation (2.45 GHz) which, for temperature equivalence, greatly accelerates the diffusion of ethylene oxide (EO) in polymeric materials compared to that using conventional heating. The mechanism of action was investigated in detail by examining the desorption of EO from polyvinylchloride (PVC). The diffusion coefficient was found to be dependent upon diffusant concentration. (Edited author abstract) 12 refs.

**082670 DETERMINATION OF THE RADIATION YIELD OF HYDROGELS CROSSLINKING.** The ability of polymer to crosslink on exposure to radiation is frequently represented by a G value, the number of crosslinks per 100 eV absorbed. Several methods are available for its determination, the most frequent being the dose D $_g$  required to form an incipient network since (with many systems) this corresponds to one crosslinked unit per weight average molecular. Its determination therefore depends on a knowledge of the molecular weight of the starting polymer. An alternative method, far less frequently used, is to measure the degree of swelling of a crosslinked network. It is shown that, for a series of polymers, irradiated either as liquids or in solution, the theoretical relation between swelling and crosslink density is followed, and the G(X) values derived from swelling compare well with those given in the literature, and based on gel fraction. (Edited author abstract) 15 refs.

**082671 PULSE RADIOLYSIS OF POLY(STYRENE) IN AQUEOUS SOLUTIONS.** Various radical species have been identified in the pulse radiolysis of aqueous solutions of poly(styrenesulfonate) (PSS). OH radicals react with PSS to produce predominantly a mixture of OH adducts. An intrapolymer biradical decay of the OH adducts takes place when several OH radical adducts are produced on the same polymer molecule. This decay reaction competes with a first-order formation of a positive radical ion ( $k=(160\pm40)$  s $^{-1}$  at pH 5.6). The formation reaction is acid catalyzed. It is slowed down by addition of inert salts. The positive radical ion decays in the time range of hours, obeying a first-order rate law. This decay is attributed to an intramolecular conversion of the positive radical ion to a benzyl type radical, which subsequently decays to produce stable recombination products. (Edited author abstract) 16 refs.

**082672 POLYVINYLIDENE FLUORIDE MICRO-FILTER FORMATION BY  $^{35}\text{Cl}^+$  AND  $^{58}\text{Ni}^+$  ION BOMBARDMENT AND ALKALI ETCHING.** We have studied the process of producing microfilters of polyvinylidene fluoride by Cl, Ni, and Cu ion bombardment and alkali etching. The effects of ion energy and mass on the resulting hole diameters were examined. The hole diameter perforated in PVDF increases with increasing mass and decreases with increasing kinetic energy of the ions. The hole diameters on the surface of the film change little, but the effective hole diameter, which depends on the narrowest site along the long tube, decreases with increasing kinetic energy of ion. This is inferred from the angle of taper in the canal. The axial and lateral etching rates of the long canal were obtained by measurements of gaseous flow through the holes. Clear-cut entrances for the holes were observed by SEM and the cylindrical and parallel canals were shown by TEM. The doses per film are calculated to be about 2-6 Mrad at a hole density of  $3\times10^8$ /cm $^2$ . (Author abstract) 15 refs.

**082673 METHOD FOR DETERMINING THE FRACTION OF UNREACTIVE FREE RADICALS IN IRRADIATED SOLID POLYMERS.** Free radicals are frozen into solid polymers when the latter are irradiated at liquid nitrogen temperature. On heating to higher temperatures the free radicals will then disappear by recombination. However, in some polymers some free radicals are situated in locations where they cannot react at temperatures where other free radicals in the solid do react. Equations are given for the kinetics of the decay reactions from which the fraction of the non-decaying species can be accurately calculated. From the results of this work, it appears that the new forms of the second order reaction kinetic equation enable estimates to be made of the fraction of non-decaying free radicals in irradiated solid polymers and also of the extent to which the free radical recombination reactions are diffusion controlled. 5 refs.

**082676 KINETIC STUDY OF POLYOXYETHYLENE GLYCOL CYCLIZATION UNDER CONDITIONS OF THE PFITZNER-MOFFAT REACTION.** The kinetics was studied of the polyoxyethylene glycol cyclization in the presence of dicyclohexylcarbodiimide, dimethyl sulfoxide and ortho-phosphoric acid in  $\text{CCl}_4$  at room temperature (the Pfitzner-Moffat reaction). For polymers of various molecular mass, the rate constants of this reaction were determined by IR-spectroscopy. The rate constant of oxidation of a low-molecular mass monofunctional analogue (ethanol) was determined by GLC. It was found that in all cases the constants have similar values, in the range  $(4-7) \times 10^{-6} \text{ sec}^{-1}$ . The polymer cyclization rate appears to be limited by the hydroxyl group oxidation to aldehyde. (Author abstract) 8 refs.

## Recovery

**082679 RECOVERY PROCESSES IN AMORPHOUS POLYMERS.** The release of stored energy and the recovery of dimension and volume of cold compressed polystyrene (PS), polymethyl methacrylate (PMMA) and polycarbonate (PC) were studied. The release of stored energy has two peaks, one broad peak at 70°C (PS), 55°C (PMMA) and 85°C (PC) and one sharp peak at 113°C (PS,  $T_g = 105^\circ\text{C}$ ), 123°C (PMMA,  $T_g = 117^\circ\text{C}$ ) and 157°C (PC,  $T_g = 152^\circ\text{C}$ ). The recovery of dimension has only one peak at 114°C (PS), 124°C (PMMA) and 157°C (PC). This peak agrees very well with the second peak in the release of stored energy. The recovery of volume has a broad peak similar to the first peak in stored energy. Thus there are probably two recovery processes in these polymers: one releases energy and recovers volume below  $T_g$  and the other releases energy and recovers dimension above  $T_g$ . (Edited author abstract) 48 refs.

## Reduction

**082680 ESR STUDY OF THE ELECTROCHEMICAL REDUCTION AND OXIDATION OF POLY(p-NITROSTYRENE).** Electron spin resonance (ESR) spectroscopy is applied to study the electrochemical oxidation and reduction of poly(p-nitrostyrene) solutions in situ. The electrochemical reduction in dimethylformamide solution leads to production of the anion radical of poly(p-nitrostyrene). The ESR spectrum of the reduced polymer is unusual in that it consists of a single homogeneously narrowed line, with no observed hyperfine couplings. On the basis of the temperature and concentration behavior of the ESR spectrum, it is concluded that the electron spin is involved in an intramolecular hopping along the pendant nitrophenyl groups in the polymer. At room temperature the rate of this process is approximately 55 MHz. The activation energy for this process is 1.5 kJ/mol in solution and 0.18 kJ/mol in the solid state. (Edited author abstract) 26 refs.

## Reinforcing

**082681 SELF-REINFORCED MELT PROCESSIBLE POLYMER COMPOSITES: EXTRUSION, COMPRESSION, AND INJECTION MOLDING.** Rheological properties, extrusion, fiber spinning, compression, and injection molding of blends of polycarbonate and two thermotropic liquid crystal polymers based on wholly aromatic copolyesters have been studied. Based upon differential scanning calorimetry and dynamic mechanical measurements, these blends have been shown to be incompatible in the entire range of concentrations. During extrusion and injection molding at high strain rates, it has been observed that thermotropic liquid crystal polymer at concentrations, 2.5, 5, and 10 percent by weight in situ forms high modulus and high strength fibers within the polycarbonate matrix leading to self-reinforced polymer composites. The tensile strength of the composite containing 10 percent of liquid crystal polymer exceeds that of the pure components. In addition, anisotropy of properties of the injection molded parts has been found to substantially reduce in a comparison with that of liquid crystal polymer. The processing conditions and technique for the production of self-reinforced polymer composite during processing of the blends have been identified. (Edited author abstract) 37 refs.

**082684 ACTIVATION VOLUME DISTRIBUTION OF RELAXATIONAL PROCESSES IN POLYMERS.** In this paper activation volume distributions are obtained on the basis of an analysis of thermally stimulated depolarization currents (TSD) at hydrostatic pressures up to 200 MPa in the regions of  $T_g$  ( $\alpha$ -relaxational process) for polyvinylchloride (PVC), polymethyl methacrylate (PMMA), polyvinyl acetate (PVA), polychlorotrifluoroethylene (PCTFE), and nylon 6, and also in the region of  $T < T_g$  ( $\beta$ -relaxational) in the case of PMMA. The data obtained in this work indicate that structural rearrangement which accompanies the transition from the glassy to the high elastic state and which results in a sharp increase in the amplitude of rotary segmental motions, produces narrowing of the distribution functions with respect to activation parameters and a change in their form. 15 refs.

**082685 COMPUTER SIMULATION STUDIES OF THE SOLITON MODEL: 3. NON-CONTINUUM REGIMES AND SOLITON INTERACTIONS.** The authors study of the sine-Gordon soliton model, performing stochastic molecular dynamics computer simulations for a wide range of both temperatures and coupling constants. We find three general regimes of behavior: the continuum limit or non-interacting regime; the pinned or transition-state-theory (TST) limit, where soliton-phonon interactions are important; and the general non-continuum regime, where soliton-soliton interactions of 'multiple soliton effects' are important. In the non-continuum regime, the correlation function changes as a function of temperature and coupling constant. We expect that this will lead to deviations from the continuum limit temperature scaling and soliton energy scaling observed in the dynamics of sine-Gordon systems. (Edited author abstract) 20 refs.

**082688 STUDIES OF SYNTHETIC POLYMERS BY NONRADIATIVE ENERGY TRANSFER.** Non-radiative energy transfer between fluorescent labels attached to polymers has been used to characterize polymer miscibility, the interpenetration of chain molecules in solution, micelle formation in graft copolymers, the unfolding of collapsed chain molecules in polymer melts, and the transfer of energy absorbed by a large number of donor labels to a small number of acceptors by an 'antenna effect.' The change in the emission spectrum after ionomer solutions with different fluorescent counterions were mixed provided rate constants for counterion interchange. The fluorescence behavior of dispersions of donor-labeled polymers stabilized by a graft copolymer with acceptor fluorophores in the solution phase led to inferences about the morphology of the dispersed particles. (Author abstract) 47 refs.

Morawetz, Herbert (Polytechnic Univ, Brooklyn, NY, USA). *Science* v 240 n 4849 Apr 8 1988 p 172-176.

**082689 STUDY OF POLYMER/WATER INTERACTIONS USING SURFACE ACOUSTIC WAVES.** Application of surface acoustic waves to the study of fundamental properties of hygroscopic polymer/water systems is reported. The basic device used is a surface acoustic wave (SAW) delay-line oscillator, the propagation path of the delay line being coated with a film of the polymer to be studied. The frequency of the SAW oscillator is measured as a function of temperature at various relative humidities. Thermodynamic functions of free energy, enthalpy, and entropy are then determined. The transient response of the SAW oscillator to step changes in humidity is also studied, and may be described by a generalized relaxation equation containing two additive terms. The utility of these data for analyzing the thermodynamics and kinetics of water-vapor sorption and desorption is discussed. (Edited author abstract) 34 refs.

Brace, John G. (Johnson Controls Inc, Milwaukee, WI, USA); Sanfelippo, Thomas S.; Joshi, Shrinivas G. *Sens Actuators* v 14 n 1 May 1988 p 47-68.

**082690 DEVELOPMENT OF LOOPS, TRAINS, AND TAILS IN A SELF-AVOIDING POLYMER SEQUENCE AT A RIGID BOUNDARY AS A FUNCTION OF SOLVENT COMPOSITION.** The development of loops, trains, and tails in a self-avoiding hard-sphere sequence terminally attached to a rigid boundary is determined as a function of solvent particle diameter, packing fraction, and chain length: the analysis is made on the basis of the convolution integral approximation. It is found that the introduction of a solvent drastically modifies their development in comparison to the zero solvent case, and the results are analyzed in terms of the attritional processes associated with the introduc-

tion of the boundary and the replacement of segment by solvent particles. (Author abstract) 9 refs.

Croton, Clive A. (Univ of Newcastle, Newcastle, Aust). *Macromolecules* v 21 n 1 Jan 1988 p 244-249.

**082691 HOW DOES THE POLYMER MAIN CHAIN INFLUENCE THE SIDE-CHAIN MOBILITY? A FLUORESCENCE PROBE STUDY BY MEANS OF TWISTED INTRAMOLECULAR CHARGE-TRANSFER PHENOMENA.** The authors prepared poly(methyl methacrylate) (PMMA) containing a very small amount of DMAB chromophore attached to the side chain via an alkyl chain of variable length. Close study of TICT (Twisted Intramolecular Charge-Transfer) fluorescence in dilute solution revealed that the fluorescence behaviors are dependent on the length of spacer as well as on the chain conformation. It is apparent that small rotational motion in the side chain is controlled by the polymer main chain even in very dilute solutions. 17 refs.

Tazuke, Shigeo (Tokyo Inst of Technology, Yokohama, Jpn); Rong Kun, Guo; Hayashi, Ryuichi. *Macromolecules* v 21 n 4 Apr 1988 p 1046-1051.

**082692 MOLECULAR MOTIONS IN MODEL NETWORK POLYMERS.** Molecular motions in network polymers of monodisperse PPO,  $\alpha,\omega$ -dihydroxypropylene oxide, cross-linked with TIPTP, tris(4-isocyanatophenyl) thiophosphate, were compared with those of linear polymers of the same molecular weight PPO chains extended with diisocyanates. The linear polyurethanes have a single exponential decay for  $T_{1\rho}(C)$  with well-defined  $T_{1\rho}(C)$  minima that occur at lower temperatures for longer PPO segments. Samples of 1000 MW PPO chains extended with phenylene-1,4-diisocyanate show the same  $T_{1\rho}(C)$  values by cross polarization or direct polarization while these values are different for toluene-2,4-diisocyanate linked polymers, indicating the presence of regions of dissimilar rigidity. (Edited author abstract) 27 refs.

**082694 MANIFESTATION OF REPTATION MOTIONS OF MACROMOLECULES ON DIFFUSIONAL ATTENUATION OF THE STIMULATED SPIN ECHO SIGNAL.** The effect of fluctuations in the characteristics time of motion of defects and the length of the force pipe on the diffusional attenuation profile of the spin echo signal in the long wave region is discussed. When the correlation times of these fluctuations are more than the average time of pipe regeneration the diffusional attenuation has an essentially non-exponential character and can be described in terms of a random fluctuating coefficient of self-diffusion. The true coefficient of self-diffusion can be determined from the initial inclination of the diffusional attenuation profile. (Author abstract) 10 refs.

Fatkullov, N.F. (V.I. Ulyanov-Lenin State Univ, Kazan, USSR). *Polym Sci USSR* v 29 n 2 Feb 1987 p 447-454.

**082695 EFFECT OF PLASTICIZATION ON MASS DIFFUSION OF CAMPHORQUINONE IN POLYSTYRENE.** Mass diffusion coefficients of camphorquinone (CQP) in the polystyrene-diethyl phthalate (plasticizer) system are measured at various temperatures and concentrations of diethyl phthalate (DOP) by using the laser-induced holographic grating relaxation technique. The mass diffusion coefficient of CQP shows a strong dependence on the concentration of DOP, which is explained in terms of the free volume increase introduced by the plasticizer. At a given temperature, the diffusion coefficient of CQP in polystyrene (PS) containing 12.4% of DOP is more than  $10^4$  times higher than that in pure PS. The apparent activation energy is found decreasing as the plasticizer concentration increases. (Author abstract) 6 refs.

**082696 EFFECT OF AN INHOMOGENEITY ON LOCAL CHAIN DYNAMICS: CONFORMATIONAL AUTOCORRELATION FUNCTION.** The influence of an inhomogeneity such as a fluorescence or ESR label on local polymer main chain dynamics is investigated theoretically by using a bistable conformational model including isolated transitions and correlated pair transitions. The conformational autocorrelation function is determined by a perturbative treatment within the limit of a far chain end inhomogeneity. The model suggests two types of behavior according to the dynamic properties of the inhomogeneity. A flexible inhomogeneity yields a decrease of the cooperative relaxation time and an increase of the main-chain mobility while the opposite case is obtained with a rigid one. The results are compared with Hall-Helfand's model, generalized diffusion and loss model, and the recent study of B.B. Pant et al. relative to the effect of a probe on polymer chain dynamics. (Edited author abstract) 8 refs.

**082699 POLYUREAS CONTAINING DIAZA CROWN ETHER UNITS: SYNTHESIS AND INFLUENCE OF RING SIZE ON THE GLASS TRANSITIONS AND SECONDARY RELAXATION PROCESSES.** A series of polyureas have been prepared by linking together diaza crown ether units of sizes 12, 18, and 24 atoms by using diisocyanates of differing rigidity. Measurement of the glass transition temperature,  $T_g$ , showed that as the ring size increased from 12 to 24 atoms,  $T_g$  decreased in polymers with a common linking unit. When the ring size was held constant,  $T_g$  varied with the flexibility of the spacing unit. Several secondary relaxations were located. It was possible to identify intramolecular relaxation processes in the diaza crown ring that occurred at decreasing temperatures as the ring size increased in the order 200 K (12-crown) > 152 K (18-crown) > 148 K (24-crown) when methylenedi-p-phenylene diisocyanate was the linking unit. (Edited author abstract). 15 Refs.

**082700 EFFECT OF LATTICE COORDINATION NUMBER ON THE DYNAMICS OF MODELS OF DENSE POLYMER SYSTEMS.** Dynamic Monte Carlo simulations of both simple cubic and face-centered cubic lattice models of dense polymer systems have been performed and analyzed by studying the autocorrelation functions of the first three Rouse coordinates. A significant difference between the two lattices is found in the concentration dependence of the scaling exponent that describes the chain length dependence of the relaxation times. This difference is due to the necessity of using bead movement rules with two different length scales in the simple cubic lattice model, while in the face-centered cubic model elementary motions with a single length scale are sufficient. Implications of this result are discussed. The normal mode analysis also provides some insight into the nature of the entanglement constraint in dense polymer systems. (Author abstract). 19 Refs.

**082701 POLYARYLATES. V. THE INFLUENCE OF PHASE TRANSFER AGENTS ON THE INTERFACIAL POLYCONDENSATION.** The effect of various phase transfer agents on the interfacial polycondensation of bisphenol A with isophthaloyl chloride was investigated. It was found that the transfer rate of bisphenolate and, thus, the reaction rate of polycondensation were increased with an increasing lipophilicity of the phase transfer agent, i.e. TBAC > TEAC > TEAC, whereas the equilibrium of bisphenolate between the organic phase and the aqueous phase was hardly affected. Moreover, experimental evidence indicated that a phase transfer agent of high lipophilicity reduced the hydrolysis of the acid chloride, an important aspect in interfacial polycondensation. (Author abstract). 7 Refs.

**082702 KINETICS OF EXCIMER FORMATION IN CHOLESTERIC MESOPHASES CONTAINING CHOLESTERYL 3-(1-PYRENYL)PROPANOATE.** The kinetics of excimer formation in cholesteric liquid crystalline (CLC) mixtures containing 3-25 mol % of cholesteryl 3-(1-pyrenyl)propanoate (Py-2) was examined. Fluorescence rise and decay curves of monomer and excimer emissions were fitted to the Birks kinetics, and the elementary rate constants were determined at different temperatures in the cholesteric and isotropic phases. The rate constant of excimer formation was much smaller than that reported for a dilute solution of pyrene and a little smaller than that for pyrene molecules dispersed in a CLC mesophase. Only a small effect of the phase change from cholesteric to isotropic was observed on the excimer formation rate constant. But the activation energy for the excimer dissociation was significantly decreased in the cholesteric mesophase. (Edited author abstract). 12 Refs.

**082703 EXCIPLEX FORMATION IN CHOLESTERIC LIQUID CRYSTALS CARRYING CARBAZOLYL AND TEREPHTHALOYL GROUPS.** Exciplex formation was observed in cholesteric liquid crystals (CLCs) containing cholesteryl 3-(9-carbazolyl)propanoate (9Cz-2) or 3-[3-(N-ethylcarbazolyl)propanoate (3Cz-2)] as a donor, and cholesteryl methyl terephthalate (CMT) or dimethyl terephthalate (DMT) as an acceptor. The exciplex formation was more efficient when CMT was used as an acceptor than when DMT was used. The efficient exciplex formation of CMT in the CLC phase was interpreted by an arrangement of terephthaloyl groups of CMT molecules close to carbazolyl groups. An exciplex of high energy was detected when 9Cz-2 was used as the electron donor and CMT as the acceptor. The high-energy exciplex was observed only in the CLC phase at low temperatures. It was concluded that a constraint on the orientation of carbazolyl and terephthaloyl groups in the CLC phase leads to the unstable exciplex, which cannot be formed in isotropic media. (Edited author abstract). 17 Refs.

**082705 EFFECT OF POLYMER BRIDGING ON THE FLOCCULATION KINETICS OF COLLOIDAL DISPERSIONS.** Relative coagulation and flocculation rates of negatively charged colloidal dispersions (silver iodide sol, arsenic trisulphide sol, polystyrene latex) in the presence of electrolyte and small amounts of methylcellulose (MC), polyvinyl pyrrolidone (PVP) or 1:1 (w/w) MC-PVP mixture, have been determined by measuring the change in optical density of the dispersion with time. It was found that the adsorbed polymer may enhance or diminish the rate of successful encounters between particles, even at low surface coverages, depending on the magnitude of the interparticle electrostatic repulsion. (Edited author abstract) 17 Refs.

**082706 NOVEL METHOD TO STUDY POLYMER INTERFACIAL DYNAMICS.** The author's have developed a technique to determine the rate of reconfigurations of polymers on surfaces. The principle of this measurement is to study the streaming potential of a capillary and then to inject polymer into the electrolyte stream in short pulses. The streaming potential essentially gives the hydrodynamic layer thickness, and one observes, between pulses, the time dependence of the adsorbed layer thickness as it approaches the equilibrium state. The results are indicative of an unfolding going on (10 to several hundred seconds) and were found to depend strongly on effective segmental adsorption energy.

**082710 CONSTRUCTIONS OF MASTER CURVES AND MASTER SURFACES STARTING WITH EXPERIMENTAL DATA.** Starting with the theoretical considerations of authors' previous papers, some practical aspects concerning the shift procedures of rheological data are analysed. The latter can be used for the construction of both isotherm and isochrone master curves as well as of master surfaces, with the condition of experimental verification of the validity of the time-temperature superposition principle. Thereby any empirical shift procedure is omitted. Examples are presented for a very large frequency-temperature range, including the glass transition zone. (Edited author abstract) 5 refs.

**082711 SIMULATION OF PLANAR WELDING FLOWS: PART 2. STRAIN HISTORY, STRESS CALCULATION, AND EXPERIMENTAL COMPARISON.** Welding flows occur in polymer processing when two streams of molten polymer meet to form a weld interface. In this paper, a numerical method is described for calculating the stress a viscoelastic melt exhibits in a flow, based on approximate kinematics. The method assumes that the kinematics are reasonably close to those of a shear-thinning fluid such as the Carreau model. The strain history of a given flow and the resulting stress are calculated via a tracking method from finite element kinematics. Full-field flow birefringence experiments were done for low-density polyethylene and polystyrene flowing past a thin plate divider in a 1.254-mm planar slit die. By digitally analyzing birefringence photographs of the flow field, the birefringence was measured over two dimensions. The flow fields were most highly oriented in a region surrounding the weld interface just downstream of the plate divider. (Edited author abstract) 25 refs.

**082712 PREDICTION OF ELASTIC STRAINS OF POLYMER MELTS IN SHEAR AND ELONGATION.** The aim of this paper is to relate recoverable strains in shear and elongation to the relaxation time spectrum of the melt. For that purpose, the state of stress for a given strain history is calculated on the basis of a single integral constitutive equation with strain-dependent memory function as proposed by Wagner (cf. Refs. 2 and 3). In the limit of small shear or elongation rates, this reduces to Lodge's rubberlike liquid constitutive equation (cf. Ref. 4). 42 refs.

**082713 MAXIMUM LOADING LEVELS IN FILLED LIQUID SYSTEMS.** Ouchiya and Tanaka have recently published a series of articles aimed at estimating the porosity of random packings of spherical particles having various sizes, and it is the purpose of this note to show that their work can be applied directly to the prediction of  $\phi_m$  in polydisperse suspensions, given the  $\phi_m$  for the monodisperse samples. This procedure is illustrated using the suspension viscosity data obtained by Chong et al. 11 refs.

**082715 STUDIES ON THE TRANSIENT SHEAR FLOW BEHAVIOR OF LIQUID CRYSTALLINE POLYMERS.** First, we want to determine whether the transient shear flow properties of liquid crystalline polymers are due to orientation changes of the rigid molecules or some other structural changes. Second, we would like to know whether the theories of Ericksen and even Leslie and Ericksen can at least qualitatively account for the transient behavior of LCP's. In this paper we present studies on the steady and transient shear flow properties of a thermotropic copolyester of 60- and 80-mole% PHB/PET and a lyotropic system of PPT in 100% H<sub>2</sub>SO<sub>4</sub>. We compare these results with the predictions of Ericksen's transversely isotropic fluid theory. 22 refs.

Viola, G.G. (Virginia Polytechnic Inst & State Univ, Blacksburg, VA, USA); Baird, D.G. *J Rheol* v 30 n 3 Jun 1986 p 601-628.

**082716 RHEOLOGICAL PROPERTIES OF POLYMERIC LIQUID CRYSTALS.** The theoretical framework of Doi and Marrucci for predicting the rheological properties of polymeric liquid crystals is considered in some detail. Previous limitations of the analysis, which restricted the theory to asymptotically low deformation rates, have been removed. The resulting predictions were compared with experimental data using both shearing and extensional flow configurations; for the latter a new fiber spinning apparatus was constructed with an order-of-magnitude increase in sensitivity over that of the best previously reported extensional devices. The agreement between theoretical prediction and experimental result is excellent for steady state deformations over the full range of conditions studied for both extensional and shearing modes of deformation. However, this excellent agreement between theory and experiment does not appear to extend to transient behavior, nor is it expected at very high deformation rates. (Edited author abstract) 47 refs.

**082717 EXAMPLE OF SPONTANEOUS SYMMETRY BREAKING IN POLYMER PHYSICS.** A polymer chain subject to certain constraints (slip-link plus fixed end points) is considered. It is shown that this system exhibits spontaneous symmetry breaking when the end-to-end distance of the chain is lowered below a certain critical value. Various implications of this effect are mentioned. (Author abstract) 6 refs.

Rieger, J. (Univ des Saarlandes, Saarbruecken, West Ger). *Polym Bull (Berlin)* v 18 n 4 Oct 1987 p 343-346.

**082718 COMPARISON OF SIMPLE CONSTITUTIVE EQUATIONS FOR POLYMER MELTS IN SHEAR AND BIAXIAL AND UNIAXIAL EXTENSIONS.** Experimental melt data are compared with differential constitutive equations that contain only a single adjustable parameter, besides the parameters describing the linear relaxation spectrum. The deformations are step shear, step biaxial extension, and start up of steady uniaxial extension of HDPE without long side branches and LDPE with long side branches. The Johnson-Segalman and White-Metzner models fail to predict the experimental data accurately. The equation of Acierno et al. shows strong oscillations in elongation and shear. The Giesekus equation fits the uniaxial extension and shear data but fails to do so for biaxial extension regardless of the choice of the adjustable parameter. The models of Phan-Thien and Tanner and of Larson seem to fit the data best. These two equations give a reasonably good fit to the data in all three deformations for the HDPE for a single value of the adjustable parameter. For the branched LDPE, a fit is only obtained if the parameter is separately adjusted for each of the three types of deformation. (Edited author abstract) 20 refs.

**082719 MODEL OF DILUTE POLYMER SOLUTIONS WITH HYDRODYNAMIC INTERACTION AND FINITE EXTENSIBILITY. I. BASIC EQUA-**

**TIONS AND SERIES EXPANSIONS.** A bead-spring chain model is used to describe dilute polymer solutions. Two important effects, the hydrodynamic interaction between the beads of a single chain and the finite extensibility of the springs connecting the beads, are treated in a self-consistently averaged form. For the resulting model, a rheological equation of state, a third-order retarded-motion expansion, and a second-order codeformational memory-integral expansion are derived. Furthermore, the parameters characterizing the model and the limit of infinitely long chains are discussed in great detail. (Author abstract) 64 refs.

Ottinger, Hans Christian (Univ of Wisconsin-Madison, Madison, WI, USA). *J Non Newtonian Fluid Mech* v 26 n 2 Dec 1987 p 207-246.

**082720 RHEOLOGICAL PROPERTIES OF THERMOTROPIC LIQUID CRYSTALLINE AROMATIC COPOLYESTERS.** A series of thermotropic liquid crystalline polyesters based on p-acetoxybenzoic acid, naphthalene dicarboxylic acid, hydroquinone diacetate, and poly(ethylene terephthalate) were prepared via melt polycondensation. The anisotropic melts were studied by means of thermal optical testing, differential scanning calorimetry, scanning electron microscopy, x-ray diffraction, and rheological methods. It was found that the copolymers in the mesomorphic state exhibit drastic shear-thinning and the experimental results indicate that the non-Newtonian Index  $n$  is in the range of 0.17 to 0.50, the flow-activation energies  $\Delta E$  are 297.1 to 182.0 KJ/mol over the shear rate of 10 to 1000 S<sup>-1</sup> at temperature 225 to 270°C; and the mesomorphic copolymers are readily oriented during processing, resulting in highly oriented as-spun fibers. (Author abstract) 14 refs.

**082721 TIME-TEMPERATURE SUPERPOSITION IN NONISOTHERMAL FLOW.** The principle of time-temperature superposition provides the basis for understanding how rheological properties of polymeric liquids vary with temperature. However, the formulation of this principle and its justification by overwhelming experimental evidence are for isothermal flows only. As the molecular theory justification for time-temperature superposition in isothermal flow is provided by the Rouse theory, the author explores the implications of that theory in nonisothermal flow. 11 refs.

Wiest, John M. (Univ of Sydney, Sydney, Aust). *J Non Newtonian Fluid Mech* v 27 n 1 Feb 1988 p 127-131.

**082722 FULLY DEVELOPED MULTILAYER POLYMER FLOWS IN SLITS AND ANNULI.** A numerical method has been developed for simulating fully developed multilayer shear flows of non-Newtonian fluids with arbitrary viscosity functions. Poiseuille and combined Poiseuille/Couette flows in both slits and annuli may be modeled. The method employs a finite difference system where grid points lie on streamlines and move to their correct positions as the solution procedure converges. Interfaces are easily handled as particular streamlines with the equation of motion replaced by a boundary condition. The method is stable for high interface viscosity ratios and readily handles a large number of layers. Many authors have employed power law models to model multi-layer non-Newtonian flows. We find that the power law is sufficient to predict pressure gradients and interface positions in most cases, but gives unrealistically flat velocity profiles, even when truncated at finite viscosity. Results are presented for the Carreau fluid and for the rubber-like liquid with shear thinning via Wagner's strain functional. (Author abstract) 21 refs.

Nordberg, M.E. III (Univ of Massachusetts, Amherst, MA, USA); Winter, H.H. *Polym Eng Sci* v 28 n 7 Mid-April 1988 p 444-452.

**082723 MOLECULAR RHEOLOGY OF H-POLYMERS.** The rheological behavior of branched polymer melts contrasted with that of linear melts motivates a discussion of a molecular model of a melt of H-polymers. Concentrating on the dynamics of the 'backbone', we derive and discuss the linear viscoelastic properties in the light of experiments by J. Roovers. The model is extended to treat nonlinear deformations, with path-length extension treated in a self-consistent way, and compared with rheological behavior of branched LDPE. (Edited author abstract) 34 refs.

**082724 RHEOLOGICAL PROPERTIES OF POLY(1,3-DIMETHYL-1-BUTENYLENE) AND MODEL ATACTIC POLYPROPYLENE.** A series of atactic polypropylene polymers were prepared by anionic polymerization of 2-methyl-1,3-pentadiene followed by saturation with hydrogen. The polymers were nearly monodisperse in molecular weight distribution and covered a wide range of molecular weights. Measurements before and after hydrogenation were used to establish the molecular weight and temperature dependence of rheological properties. When the results were compared with data on commercial isotactic polypropylene it was found that the viscosities of the two types of polymers are essentially the same. (Edited author abstract) 37 refs.

**082726 REOLOGICZNY MODEL MIKROSTRUKTURALNY DEGRADACJI POLIMERU W STANIE STOPIONYM.** [Rheological Microstructural Model of the Mechanical Degradation of Polymer Melts]. The rheological constitutive equation was derived for polymer melt undergoing the mechanical degradation. For the calculation of polymer molecules motion and its contribution to the stress tensor, the statistical methods were applied using probability distribution function of the polymer chains. The continuity equation and the equation of balance of forces influencing the motion of the statistical molecule were formulated taking into account the assumptions concerning mechanism of the chain shortening. A definition of structural parameter was stated as a measure of the degradation degree and the relationship between it and the number-average molecular weight was determined. The rheological constitutive equation derived in this way was verified in the simple shearing experiment. (Author abstract) 16 refs. In Polish.

**082727 THEORETICAL STUDY OF NON-ISOTHERMAL MULTI-LAYER STRATIFIED FLOWS BETWEEN PARALLEL PLATES.** An implicit finite difference method with the stream function as the cross-stream coordinate has been employed to study non-isothermal multi-layer stratified flows. The stream function is used to locate the interface positions so that the numerical computation for multi-layer stratified flows can be performed more efficiently. Numerical computations are made in the range,  $10^2 \leq Pe \leq 10^4$  and  $0.1 \leq Na \leq 10$ .

Several cases with various flow rate ratios and non-uniform entrance temperatures have been investigated as well. The fluid viscosity is described by the power law for the shear rate dependence and by the Arrhenius relationship for the temperature dependence. For the Nusselt number greater than or equal to unity, viscous dissipation leads to significant temperature rise adjacent to the wall. The pressure gradient along the die axis may thus be affected. (Author abstract) 20 refs.

**082728 OF SPIDERS AND SPINNING.** Many fluids used in the chemical industry have peculiar flow properties, especially polymer melts and solutions. The processes of blow molding films, spinning fibers, vacuum forming sheets and flow through porous media are all controlled mainly by elongational flow (stretching). Even spiders depend upon this phenomenon to make their webs. Elongational measurements are, however, tricky to make and special techniques are needed to help chemists to understand these flow properties. (Author abstract) 3 refs.

**082729 RHEOLOGY OF A TWIN LIQUID CRYSTALLINE POLYMER.** Phase transitions of a twin liquid crystalline polymer (TLCP), which was synthesized from 4-[(4'-alkoxybenzoyloxy)benzoyl chloride and  $\alpha,\omega$ -dihydroxy-telechelic polytetrahydrofuran, have been determined by measurements of linear viscoelastic properties. In the phase-separated mesophase state, the TLCP displayed high elasticity to small-amplitude deformation, due to mesogen-induced physical cross-linking. As the strain amplitude increased, shear thinning affected both dynamic and steady flow properties. This effect is assumed to be due to a reduction of tie molecules and an increase of loops in the physical network. (Edited author abstract). 18 refs.

**082730 RHEOLOGICAL PROPERTIES OF LINEAR LOW DENSITY POLYETHYLENE/POLYPROPYLENE BLENDS. PART 2: SOLID STATE BEHAVIOR.** This second paper of a series continues the examination of the tensile properties of two series of linear low density polyethylene/polypropylene (LLDPE/PP) blends. The blends were prepared using a twin-screw extruder and cover the whole concentration range. An Instron Universal Tensile Tester was used to measure the tensile properties of the blends between 10 and 70°C, and the temperature and composition dependences of the modulus were examined. A comparison is established between the solid state and melt properties to underline the behavior in the PP rich region. Results of dynamic mechanical experiments and differential scanning calorimetry on the same materials are also given, and the mechanical behavior is discussed in terms of the variation of the system's crystallinity. (Author abstract) 20 refs.

## Separation

**082731 PHASE SEPARATION OF POLYMER MIXTURES IN THE PRESENCE OF SOLVENT.** A model of a symmetrical polymer mixture, where both polymers A and B are modeled by self-avoiding walks of  $N_A = N_B = N$  steps on the simple cubic lattice and a lattice site is taken by either an A monomer, a B monomer, or a solvent molecule (or a vacancy V, respectively), is analyzed by Monte Carlo simulations, in order to analyze the validity of the predictions of the Flory-Huggins theory. We attribute huge discrepancies found between the

'exact' critical temperature of phase separation for this model and those predicted by the Flory-Huggins approximation to the crude treatment of chain configurational statistics in this approximation. We also obtain binodal curves and a scattering function and discuss the crossover from Ising-like critical behavior to mean-field critical behavior as  $N$  approaches  $\infty$ . Consequences for experimental work are briefly discussed. (Edited author abstract) 71 refs.

Sariban, A. (Johannes-Gutenberg-Univ Mainz, Mainz, West Ger); Binder, K. *Macromolecules* v 21 n 3 Mar 1988 p 711-726.

**082732 PRESSURE-PULSE-INDUCED CRITICAL SCATTERING OF OLIGOSTYRENE IN N-PENTANE.** An experimental method has been developed for the determination of binodal and spinodal points in the temperature-pressure-concentration phase diagram of demixing systems. Intensities of scattered and transmitted light are measured as a function of pressure. It is shown that the intensity of the experimentally determined scattered light is completely different from the corrected light scattering intensity, which is calculated by turbidity corrections. Slow changes of the pressure can be used for isothermal experiments and fast pressure pulses for adiabatic procedures. These methods based on the theory of Debye are explained for two concentrations of the system oligostyrene/n-pentane. (Author abstract) 75 refs.

**082733 GASCHROMATOGRAPHISCHE TRENNUNG VON ETHOXYLIERTEN ALKOHOLEN.** [Separation of Polymer Homologues of Low Ethoxylated Alcohols by GLC]. GLC analysis of non-derivatized ethoxylated fatty alcohols (alkyl =  $C_8, C_{12}, C_{16}$ ) on short, packed columns was investigated. Retention times of the polymer homologues with identical alkyl chain up to MW 500 depend linearly on ethoxylation degree. Because peak areas, corrected by FID factors, correspond to the mol ratios a quantitative evaluation is possible. The reliability of the obtained results was examined by defined test compounds. (Author abstract). 11 refs. In German.

**082734 SOLUBLE POLYMERS IN ORGANIC CHEMISTRY: 5. PREPARATION OF CARBOXYL- AND AMINO-TERMINAL POLYETHYLENE GLYCOL OF LOW MOLECULAR WEIGHT.** The transformation of polyethylene glycol monomethyl ether (MPEG-OH), of molecular weight 550 to carboxyl- and amino-terminal derivatives is described. Applying polymer-analogous reactions for the functionalization, the final products are isolated by pH-controlled extraction procedures. The surprisingly high solubilizing power in water together with their convenient handling demonstrates, that reactive polyethylene glycols of low molecular weight have considerable potential for applications in organic and biorganic chemistry. (Author abstract) 14 refs.

**082735 DETERMINATION OF SOLUBILITY PARAMETER OF POLYMER BY MICROWAVE ABSORPTION IN WAVEGUIDE.** Microwave absorption of mixed solutions of: 1) the hydrogen bonding solvents (methanol, ethanol, propanol, butanol, amyl alcohol, and octyl alcohol) and each of a number of hexane, carbon tetrachloride, benzene, and methanol; and 2) aprotic polar solvents (nitromethane, acetonitrile, nitrobenzene, and

dimethyl sulfoxide) and polar or nonpolar solvents was measured at 9.3 GHz in a waveguide. At the same time, the magnitude of microwave decayed energy by various solvents in polymer films at 9.3 GHz was estimated. We estimated the solubility parameter of various polymers: polystyrene, poly(butadiene), poly(vinyl alcohol), and nylon-6,6. The results suggest that the microwave absorption is dependent on a hydrogen bonding or a dipole-dipole interaction between the polymer and solvent. (Edited author abstract) 14 refs. In Japanese.

**082736 DIFFUSION IN CONCENTRATED POLYMER SOLUTIONS: ENCAPSULATED FENE DUMBBELL MODEL RESULTS.** Structure-property relations for the encapsulated FENE dumbbell correlate well with experimental observations for concentrated polymer solutions. Relying on rigorous kinetic theory results, we derive an expression for the polymeric mass flux relative to the mass-average velocity (diffusive flux). The form of this flux implies non-Fickian diffusion with its own intrinsic time scale. For steady flow in an infinitely long tube nonuniform concentration profiles are predicted. (Author abstract) 14 refs.

**082737 OPTICAL PROPERTIES OF SOLUTION OF POLYTHIOPHENE DERIVATIVES AS FUNCTIONS OF ALKYL CHAIN LENGTH, CONCENTRATION AND TEMPERATURE.** Optical transmission through the cell of solutions of polythiophene derivatives such as poly(3-octylthiophene), poly(3-dodecylthiophene) and poly(3-dodecylthiophene) has been found to change drastically with temperature and concentration. This transmission change is also dependent on the alkyl chain length. The critical temperature of  $T_c$  of the transition between two transmission states (opaque and transparent) increases with increase in both concentration and chain length. This phenomenon has been conjectured to originate in the change of light scattering due to some conformational transition of polymers in the solvent. An application of this phenomenon has also been proposed. (Author abstract) 10 refs.

**082738 MICROCELLULAR FOAMS: PHASE BEHAVIOR OF POLY(4-METHYL-1-PENTENE) IN DIISOPROPYLBENZENE.** Microcellular foams are an important component of Inertially Confined Fusion (ICF) targets. The spatial distribution of the material is critical as the target implodes. In an effort to improve the spatial uniformity, the authors have explored the phase separation behavior of poly(4-methyl-1-pentene) solutions with diisopropylbenzene solvent. The cloud-point phase-separation diagram from pure solvent to pure polymer is discussed. Microstructures of the various density foams and the need for a three-dimensional phase diagram are presented. (Edited author abstract) 19 refs.

**082739 CONCENTRATION, TEMPERATURE AND DEFORMATION EFFECTS IN CONCENTRATED POLYMER SOLUTIONS WITH VOLATILE SOLVENTS.** A novel high-pressure polymer solution viscometer has been experimentally evaluated using the polystyrene/ethylbenzene system. The polymer solutions range in concentration from 60 weight percent polystyrene to the pure melt. The overall temperature range is 132°C to 240°C. The shear rates range from roughly  $5 \text{ s}^{-1}$  to  $2000 \text{ s}^{-1}$ . It has been concluded that the present method is useful in determining the shear dependent behavior of these volatile solutions. The shear dependent nature of this system is consistent with accepted non-Newtonian viscosity theory. (Author abstract) 16 refs.

**082742 ON POLYMER SOLUTION THERMODYNAMICS.** Various solution properties have been selected for testing the usefulness of the classic lattice model. The analysis leads to the inclusion of improvements such as different contact numbers for molecules and repeat units, distinction between concentration regimes, dilute and concentrated in polymer. The extensions of the simple model supply an adequate description of the data provided the free enthalpy of mixing in the concentrated region is made temperature- and molar mass-dependent. Part of the latter contribution can be attributed to the chains bending back on themselves. The other part is not easily accommodated in the model and might be related to free volume effects that have been left out of the present consideration. (Edited author abstract) 65 refs.

**082743 ADSORPTION-ENTANGLEMENT LAYERS IN FLOWING HIGH-MOLECULAR WEIGHT POLYMER SOLUTIONS.** This work is concerned with the formation and nature of thick multimolecular layers and with the effect they have on fluid transport in general and viscosity measurements in particular. In the present first part the existence of such layers is established through a flow visualization method and the layer formation diagnosed in situ is correlated with macroscopic flow

effects. Two flow geometries are used, Couette and channel flow. It is demonstrated that owing to the fact that adsorption entanglement layers alter the geometry of the flow channel the time dependence of flow effects, per se need not indicate shear thickening (or thinning), in fact that there is any departure from Newtonian flow behaviour. (Edited author abstract) 32 refs.

**082745 PROPERTIES OF CELLULOSE ACETATE BUTYRATE FILM OBTAINED BY FORCED LEVELING OF A CONCENTRATED SOLUTION.** The purpose of this work was to examine the possibility of forming cellulose acetate butyrate films for optical purposes with the aid of the so-called 'leveling rule' and to study their properties. The optical, mechanical, and shrinkage properties of CAB films are given. Light transmission of all the films is high and in distinction from films described earlier, it is independent of the nature of the solvent medium. The probable explanation is that the procedure devised for film formation and removal of the liquid phase, and the smaller thickness of our films (70 as compared with  $150 \mu\text{m}$ ) level out the structural differences influencing the optical properties of the films. 10 refs.

**082748 ASSESSMENT OF ELONGATIONAL STRESSES OF DILUTE POLYMER SOLUTIONS AND A RELATED EXAMINATION OF SOME CONSTITUTIVE EQUATIONS.** Elongational stresses of dilute polymer solutions have been assessed by utilizing the flow through small orifices under the condition of no vortex upstream of the orifice plane. The flow was approximated with a linearly converging flow toward an apex of a cone, its propriety being confirmed by the measured velocities, and the elongational stresses were determined from the measured thrusts of dilute polymer solutions. On the other hand, elongational stresses were theoretically obtained with the modified Maxwell model and the second order fluid. A comparison was made between the experimental and the theoretical results and the following points were clarified; below the elongational rate  $2 \times 10^4 (\text{s}^{-1})$  the modified Maxwell model gives elongational stresses close to the experimentally determined ones, but above the elongational rate it deviates from the experimental results. (Edited author abstract) In Japanese. 10 refs.

**082749 EXPERIMENTAL INVESTIGATION OF TRANSITION IN PLANE POISEUILLE FLOW (2ND REPORT, DILUTE POLYMER SOLUTIONS).** Transition in dilute polymer solutions was investigated in the same manner as in the first report. At first we investigated natural transition at a minimum critical Reynolds number. The result suggested that the structural change of a turbulent spot resulted in polymer drag reduction. Subsequently, we maintained the flow laminar above the minimum critical Reynolds number and visualized the evolving process of spots artificially created in the laminar flow. The result showed that polymer additives reduced the spreading half angle. The striped streak lines of ink were observed around the spots. This phenomenon is supposedly caused by the instability of polymer solutions. (Author abstract) In Japanese. 9 refs.

**082750 PRESHEARED EXTENSIONAL FLOW OF DILUTE POLYMER SOLUTIONS.** Dilute solutions of polyethylene oxide (PEO) and polyacrylamide (PAM) were subjected to shearing and then extensional motion in order to determine the influence of prior shear on the extensional resistance of these fluids. The work was originally motivated by the explanation of drag reduction by polymer additives and so the tests were conducted in a flow cell designed to simulate the ejection event (burst) in a turbulent boundary layer flow. The results show that prior shear had a considerable effect on the PEO solutions, causing significant extensional resistance at strain rates of order  $10^2 \text{ s}^{-1}$ , while rates one order higher were necessary to generate an extensional effect when there was no prior shear. For the PAM solutions, on the other hand, extensional resistance depended only weakly on prior shear, and onset strain rates and resistance magnitudes depended more markedly on the ionic strength of the solvent. A flow visualization study revealed that the flow patterns for water and PEO solutions were the same but those for PAM solutions were always unsteady. (Edited author abstract) 24 refs.

James, David F. (Univ of Toronto, Toronto, Can); McLean, Brian D.; Saringer, John H. *J Rheol* v 31 n 6 Aug 1987 p 453-481.

**082751 STRESS JUMP AT THE INCEPTION OF SHEAR AND ELONGATIONAL FLOWS OF DILUTE POLYMER SOLUTIONS DUE TO INTERNAL VISCOSITY.** All versions of the internal viscosity (IV) model for polymer chain dynamics lead to the prediction that the inception of flow from a rest state is accompanied by a stress jump at  $t=0$ . For the general case of long chains (large number of submolecules,  $N$ ), the jump is predicted here for the onsets of simple shear flow and elongational flow at constant deformational rate. The exact model formulation (i.e., following Boijj and van

Wiechen) is used, without the need to approximate deformational velocities in the Cerf/Peterlin sense, and rigorous closed-form solutions are presented. This is apparently the only rheological prediction now available for the large  $N$  IV model using the rigorous formulation. Intermediate steps in the analysis demonstrate the extent to which the motions of beads are correlated with those of neighbors at various distances in the linear sequence. 28 refs.

**082758 STUDY OF INTERPENETRATION USING FLUORESCENCE QUENCHING OF CHROMOPHORE-LABELLED POLYMERS.** Fluorescence quenching was used to investigate the onset and extent of overlap and interpenetration in poly(vinyl methyl ether) (PVME) solutions using polystyrene with a dilute level of anthracene labeling (APS) as a probe. A low, constant concentration of APS was added to solutions varying in PVME concentration. The critical overlap concentration,  $c^*$ , was taken to be the PVME concentration at which quenching of the probe anthracene-labeled polymer molecules commenced. Variations in probe molecular weight and concentration produced no significant changes in  $c^*$  or in the rate of decrease in fluorescence intensity above  $c^*$ , lending credibility to the idea that the APS is simply probing the PVME system. The values of  $c^*[\eta]$  from these experiments were found to lie in the range of 0.87-1.7 which agrees with the results from previous studies. The sensitivity of this method to small differences in solvent quality for PVME was also investigated. (Author abstract) 32 refs.

**082759 DETERMINATION OF THERMODYNAMIC INTERACTION IN MIXED POLYMER SOLUTIONS BY A RAPID AND PRECISE OSMOTIC METHOD. THE SYSTEM DEXTRAN /POLYVINYLPYRROLIDONE/WATER.** An accurate and simple osmotic method for determination of thermodynamic interaction in ternary solutions (polymer A/polymer B/solvent) is described. The equipment consists of a membrane osmometer of a special design with small chambers and a pressure-sensing device to monitor the pressure difference across the membrane. A procedure has been developed to measure osmotic pressures up to rather high concentrations in both quasi-binary and quasi-ternary systems. The osmotic method is compared with results from light scattering. Different methods are utilized to extract ordinary virial coefficients as well as mixed

virial coefficients from the primary data. The system dextran/polyvinylpyrrolidone/water (two different molecular weights of dextran) was chosen as a model. (Author abstract) 15 refs.

**082760 POLY(SULPHOPROPYLBETAINES): 4. BINDING PROPERTIES TOWARDS REPORTER ANIONIC PROBES AND LOCAL POLARITY CLOSE TO THE ZWITTERIONIC CHAIN IN AQUEOUS SOLUTION.** The binding properties of a representative poly(sulphopropylbetaine) towards a series of optical (methyl orange (MO) and 2-(4-hydroxybenzenazo)benzoate (HABA)), fluorescent (8-anilino-naphthalene-1-sulfonate (ANS)) and chemically reactive (6-nitrobenzoxazole-3-carboxylate (S)) anionic probes have been studied in dilute aqueous solution. The slight ultra-violet spectra modification for MO and HABA, the enhanced fluorescence of ANS and the moderate increase of the decarboxylation rate of S induced by the poly(zwitterion) show that binding of the various anionic probes to the macromolecular chain actually occurs through specific ion-dipole interactions, but that the intrinsic properties of the bound species are only weakly modified with respect to those of the free ones. (Edited author abstract) 33 refs.

Zheng, Y.L. (CNRS, Strasbourg, Fr); Knoesel, R.; Galin, J.C. *Polymer* v 28 n 13 Dec 1987 p 2297-2303.

**082761 OPTICAL AND HYDRODYNAMIC STUDY OF POLY-P-DECYLSTYRENE SOLUTIONS.** The effect of the length of the aliphatic side chain of polycyclic styrenes on their interaction with solvents is considered. Because of bifilarity the rigidity of the main chain of polycyclohexylstyrene in a good solvent is higher by a factor of 1.3 than in a  $\theta$ -solvent. Evaluation of the transverse dimensions of macromolecules, their optical anisotropy, and also the splitting of the 820  $\text{cm}^{-1}$  band in the IR-spectra of poly-p-decylstyrene and its monomer indicate the low rigidity of the side chains. (Author abstract) 11 refs.

**082762 BEHAVIOUR OF A CHOLESTERIC SOLUTION OF POLY- $\gamma$ -BENZYL-L-GLUTAMATE IN AN ELECTRIC FIELD.** The electrooptic cholesteric-nematic phase transition and the appearance of electrodynamic instability in the form of domains is studied by optical polarization microscopy and small-angle polarized light scattering in a lyotropic cholesteric polymer. From the morphology point of view the stages of texture relaxation and subsequent untwisting of the cholesteric structure into the nematic structure, the process is a detailed analogue of the same magnetotropic transition. In fields close to the critical, during this transition there is a strong increase in the dispersion of the spacing of the cholesteric structure, which, it is suggested, should be taken into account in the model for the untwisting of this structure. (Edited author abstract) 7 refs.

Shepelevskii, A.A. (USSR Acad of Sciences, USSR); Aljmyan, Yu.A.; Ginzburg, B.M.; Ovsyannikova, L.A.; Vlasov, G.P.; Frenkel, S.Ya. *Polym Sci USSR* v 28 n 8 1986 p 1796-1802.

**082763 HYDRODYNAMIC PROPERTIES AND CONFORMATIONAL CHARACTERISTICS OF POLY-m-PHENYLENE ISOPHTHALAMIDE IN DIMETHYLACETAMIDE AND THE EFFECT ON THEM OF LITHIUM CHLORIDE.** The authors have investigated the fast sedimentation, translational diffusion and viscosity of solutions of poly-m-phenylene isophthalamide in DMAA in the range  $M = (4.2-230) \times 10^3$ . They obtained the equations  $[\eta] = 0.0956 M^{0.65}$ ,  $D = 1.13 \times 10^{-4} M^{-0.56}$  and  $S_0 = 1.72 \times 10^{-15} M^{0.44}$ . The hydrodynamic invariant is equal to  $A_0 = 3.4 \times 10^{-10} \text{ erg. degree}^{-1} \cdot \text{mole}^{-1/3}$ . Addition of 3% LiCl to DMAA led to rise in  $[\eta]$ , fall in the magnitude  $\eta_0 D$  and the partial

specific volume and increase by about one quarter in  $M$ . The latter tells in favour of the solvation of LiCl by the macromolecules and their swelling. However, the conformation of the macromolecule does not materially change. The length of the Kuhn segment is  $A = 40 \pm 8 \text{ Angstrom}$ . (Edited author abstract) 20 refs.

**082765 DENSITY AND THERMAL EXPANSION OF A TRIFLUOROPROPYLSILOXANE POLYMER IN SOLUTION.** The partial specific volume of polymers in solution is a quantity required for many of the standard techniques of polymer characterization. Of the siloxane family of polymers, the one most widely studied is poly(dimethylsiloxane) (PDMS). The partial specific volume has also been reported for poly(methylphenylsiloxane) (PMPS). Here, the authors report the partial specific volume and its temperature variation for another unsymmetrical siloxane polymer: poly(methyltrifluoropropylsiloxane) (PMTFPS). 8 refs.

Anon. *J Appl Polym Sci* v 35 n 1 Jan 1988 p 273-275.

**082766 DETERMINATION OF UNPERTURBED DIMENSIONS OF POLYMERS IN BINARY SOLVENT MIXTURES FROM VISCOSITY MEASUREMENTS.** Intrinsic viscosity measurements were carried out on poly(vinyl pyrrolidone) and poly(vinyl alcohol) in various solvents and solvent mixtures. Intrinsic viscosities, and the Huggins constant ( $k$ ) for representative fractions at various temperature in various solvents are given. Perusal of the result indicates that the values of the unperturbed dimension are higher in pure solvents than in solvent mixtures, in both the polymers. The changes in 'apparent' unperturbed chain dimensions, under  $\theta$ -conditions in binary solvent mixtures, are due solely to the interactions between unlike solvent molecules surrounding the chain. 11 refs.

**082767 OSMOTIC PRESSURE OF DEXTRAN T10 SOLUTIONS.** Using asymmetric cellulose acetate membranes, annealed at 75 and 85°C, the osmotic pressure of a dextran T10 solution (20 wt% dextran T10) is measured as a function of time. It is shown that the comparatively high osmotic pressure, obtained with the dextran T10 solution, is caused by the low molecular weight components of dextran T10 and not by the high molecular weight components. (Author abstract) 4 refs.

**082768 RELATIONSHIP BETWEEN DYNAMIC MECHANICAL PROPERTY AND THERMODYNAMIC INTERACTION PARAMETER OF CONCENTRATED POLYMER SOLUTIONS.** The use of concentrated polymer solutions is one of the basic techniques in the application of polymers. They may be coating materials, plasticized polymers, and oil-extended rubber. In these applications the solubility relation is one of the key requirements. The polymer-solvent interaction

is expected to influence the mechanical property of the mixture. It is the intent of this study to explore how the dynamic mechanical property is affected by the change of thermodynamic interaction parameter in concentrated polymer solutions. (Edited author abstract) 10 refs.

**082770 CLOSE ANALOGY BETWEEN THE PREFERENTIAL SOLVATION OF POLYMERS IN MIXED SOLVENTS AND ADSORPTION FROM LIQUID MIXTURES AT SOLID/LIQUID INTERFACES.** In this work a comparison of some phenomenological aspects of sorption and solvation, the role of the sorbent as a component, and a critique of the traditional plot of isotherms are discussed. It was pointed out that a sorbent-sorbate system can be characterized in a correct way only by a set of isotherms involving a limiting case when the mass of sorbent tends to zero. The treatment was extended to cases when more than one sorbent or more than two mixture components are present in the system. (Author abstract) 21 refs.

**082771 INTERACTION BETWEEN POLYVINYL-PYRROLIDONE AND SURFACTANT FROM VISCOMETRIC DATA.** The intrinsic viscosities of solutions of polyvinylpyrrolidone (PVP) in water-sodium dodecyl sulfate have been measured, for four different molecular weights of PVP, and different concentrations of sodium dodecyl sulfate at temperatures between 20 and 35°C. The exponent  $\alpha$  of the Mark-Houwink-Sakurada equation has been determined, and the values of the short range interaction parameter  $K_\theta$  and expansion factor  $\alpha_\eta$  derived. Above a certain concentration the sodium dodecyl sulfate is adsorbed on the polymer by means of hydrophobic attractions, and the consequent repulsion between anionic heads provokes expansion of the macromolecule. (Author abstract) 20 refs.

**082772 EFFECTS OF THERMODYNAMIC MODELS ON THE PREDICTIONS OF FREE VOLUME DIFFUSION THEORY FOR CONCENTRATED POLYMER SOLUTIONS.** Three thermodynamic models were used to demonstrate the effects of model choice on solvent-polymer binary diffusion coefficients predicted by free volume theory. Poly(vinyl acetate) and four solvents were used as typical solutions for these calculations. Thermodynamic models affect the predictions the most at high solvent weight fractions and for solutions which exhibit positive enthalpic interactions. For solutions dilute in solvent where Henry's law might describe phase equilibria, diffusion coefficients can be estimated without reference to thermodynamic data. (Author abstract) 35 refs.

**082774 EFFECT OF PHASE SEPARATION IN SOLUTIONS OF CELLULOSE ACETATE AND POLYARYLATE ON POROSITY AND STRENGTH OF THEIR CAST FILMS.** Phase diagrams of three-component solutions containing cellulose acetate or polyarylate F-2 have been investigated. The homogeneous region in ternary systems containing cellulose acetate gradually shrinks when acetic acid is replaced by dioxan and then by acetone. The dependences of porosity and strength of cast films on the content of water in the solution show minima and maxima: films prepared from solutions with composition lying on the binodal curve in the phase diagram have maximum porosity and minimum strength. (Author abstract) 20 refs.

**082775 SOLUBILITY AND MISCIBILITY OF POLY(ETHYL OXAZOLINE).** The solubility of poly(ethyl oxazoline) in aqueous solutions was studied. The cloud points decreased in the presence of sodium chloride but increased by the addition of tetrabutylammonium bromide or dioxane. Solution-cast films of blends of the polymer and poly(acrylic acid) were miscible, but mutual precipitation occurred in water, methanol, and dioxane. The compositions of the complexes correspond in most cases to simple molar ratios of the interacting groups. The glass transition temperatures of the complexes are higher than the values for blends of the same compositions, and the high values are attributed to hydrogen bonds acting as physical crosslinks. Complex formation also occurs when the polymer is mixed with a styrene-acrylic acid copolymer and with low weight polymers containing phenol groups. (Author abstract) 24 refs.

**082776 ON THE POSSIBILITY OF QUANTITATIVE EVALUATION OF THE POLYMER-SOLVENT INTERACTION FROM THE HUGGINS VISCOSITY CONSTANT.** The author discusses the possibility of evaluation of the 'goodness' of solvents for polymers and eventually of the extent of association in polymer-solvent systems from the Huggins constant, as a function of the viscosity expansion factor. However, this method does have some problems and therefore an analogous method has been suggested, i.e. the dependence of the Huggins constant on the slope of Heller's relationship. For non-associating systems, this dependence is defined by a generalized linear equation, which, unlike the dependence on expansion factor, is independent of both the polymer and its molecular weight. For associating systems, this dependence is described by a quadratic function. Its steepness is dependent on both the polymer and its molecular weight. (Edited author abstract) 54 refs.

**082777 INTERACTION VIRIAL COEFFICIENTS IN SOME MIXED POLYMER SOLUTIONS.** The concentration dependence of the osmotic pressure for

some aqueous ternary systems (polymer 2/polymer 4/water) has been studied up to relatively high concentrations. The interaction in the ternary systems has been evaluated in terms of mixed virial coefficients up to the third order ( $A_{24}$ ,  $A_{224}$ ,  $A_{244}$ ). Data are also given for the corresponding binary systems. The polymers used were dextran, poly(N-vinyl-2-pyrrolidone), Ficoll, hydroxypropylcellulose and ethylhydroxyethylcellulose. An analysis of the relative contributions to the total osmotic pressure of various terms as a function of concentration is made. (Edited author abstract) 21 refs.

**082778 FLORY ENTHALPY PARAMETER AT INFINITE DILUTION OF POLYMER SOLUTIONS DETERMINED BY VARIOUS METHODS.** The Flory enthalpy parameter at infinite dilution  $K_0$  was evaluated for atactic polystyrene (PS)-cyclohexane (CH) and -trans-decalin (D) systems by applying the following four methods from literature data: (1) Temperature dependence of vapor pressure and membrane osmotic pressure, (2) critical solution temperature  $T_c$  and critical solution concentration  $v_{pc}$  for a series of solutions of polymers, (3) temperature dependence of the second virial coefficient in the vicinity of the Flory theta temperature  $\theta$ , and (4) calorimetry. Excellent agreement ( $\pm 0.02$ ) was confirmed between  $K_0$  values at  $\theta$  deduced by various methods when  $M_w$  (or  $M_n$ ) of the polymer was the same. This fact strongly supports the validity of the modified Flory-Huggins solution theory, in which the polymer-solvent interaction parameter  $\chi$  depends on the polymer concentration and its molecular weight. **082780 DISSOCIATION OF 2,2'-SUBSTITUTED THIOINDIGO WHITES, AND RECOMBINATION OF THEIR RADICALS IN SOLUTION AND IN POLYMER MATRIX.** The dissociation of 2,2'-substituted thioindigo whites into captodative radicals and the recombination of these radicals have been examined in solution and in polymeric matrix. For the methyl- and ethyl-substituted TIW the quantum yield of dissociation in solution is equal to  $4 \times 10^{-4}$  and  $5 \times 10^{-4}$ , respectively. The behavior of these compounds was studied in three different matrices: polymethyl methacrylate (PMMA), polypropyl methacrylate (PPMA), and polystyrene (PST). The decay kinetics of the radicals after photolysis of the TIWs below  $T_g$  were interpreted on the basis of Waite's equations for diffused controlled reactions. (Edited author abstract) 32 refs.

**082781 VORTEX MOTION IN DILUTE POLYMER SOLUTIONS.** Vortex-dynamic equations have been derived and applied to two problems concerning annular vortices. It has been found that an important part is played by the behavior of individual vortex structures

in turbulent transport from measurements on turbulent boundary layers and friction reduction by polymers. The author presents a quasi-one-dimensional approach to vortex dynamics (vortex filaments of finite thickness) in dilute polymer solutions. This paper considers a vortex whose core is subject to a longitudinal elastic stress (the liquid is considered as incompressible). We assume as a first approximation that this stress is constant over the cross section of the core. (Edited author abstract) 15 refs.

**082783 COMPLEX FORMATION IN 2-POLYVINYLPIRIDINE-IODINE SOLUTIONS.** The purpose of this investigation was to compare the PVP-I<sub>2</sub> system with the Py-I<sub>2</sub> system in a quantitative manner. In the PVP-I<sub>2</sub> system, a polymer backbone is present and the pyridine groups are clustered. The  $((PVP)_2I^+)_n$  ions are very large. In the formula for the complex ion,  $((PVP)_2I^+)_n$ , the letters, PVP, refer to the repeat unit in the polyvinylpyridine macromolecule. It is likely that the complex ion is primarily intramolecular considering the relatively low concentration of polymer and the low mole ratio of iodine to PVP repeat units. The authors conclude from the three sets of data presented above that pyridine and 2-polyvinyl-pyridine interact with iodine in an almost identical manner. This statement applies to complex formation in nonpolar and polar solvents and to ionic dissociation in polar solvents. 10 refs.

**082784 WORMLIKE CHAIN PARAMETERS OF POLY(HEXYL ISOCYANATE) IN DILUTE SOLUTION.** Intrinsic viscosity-molecular weight relationships were determined for poly(hexyl isocyanate) in toluene and dichloromethane using a number of narrow-distribution samples covering a wide molecular weight range. The data were analyzed according to the Yamakawa-Fujii-Yoshizaki theory of viscosity of wormlike cylinders, yielding the following values for the persistence length  $q$  and molar mass  $M_L$  per unit contour length:  $q=41-34$  nm and  $M_L=730-760$  nm<sup>-1</sup> in toluene between 10 and 40°C and  $q=21$  nm and  $M_L=750$  nm<sup>-1</sup> in dichloromethane at 20°C. These parameter values are favorably compared with those reported for other solvent conditions for the same polymer. (Author abstract) 16 refs.

**082785 DOPING EFFECT IN SOLUTION OF POLY(3-ALKYLTHIOPHENE).** Poly(3-alkylthiophene) in solution can be doped just as in the case of polythiophene films, resulting in the suppression of the interband absorption and the appearance of absorption peaks in the infrared region originating in the transitions between polaron states and from the valence band to the low-lying polaron state. Enhancement of the spin density by doping

in an ESR measurement was also observed, which supports the polaron formation but not bipolaron formation. From these results, it has been clearly demonstrated that even a single polymer chain has the characteristics of conducting polymers. (Author abstract) 10 refs.

**082786 EXPERIMENTAL ESTIMATION OF ELONGATIONAL STRESSES OF DILUTE POLYMER SOLUTIONS AND RELATED EXAMINATION OF SOME CONSTITUTIVE EQUATIONS.** Elongational stresses of dilute polymer solutions have been estimated by utilizing the flow through small orifices under the condition of no vortex upstream of the orifice plane. The flow was approximated with a linearly converging flow toward an apex of a cone, its validity being partially confirmed by the measured center velocities, and the elongation stresses are determined from the measured thrusts of dilute polymer solutions. On the other hand, elongational stresses were theoretically obtained with the modified Maxwell model and the second order fluid. A comparison was made between the experimental and the theoretical results and the following points were clarified; below an elongational rate of  $2 \times 10^4 \text{ s}^{-1}$  the modified Maxwell model gives elongational stresses close to the experimentally determined ones, but above that elongational rate it deviates from the experimental results. (Edited author abstract) 16 refs.

**082787 ROLE OF SOLUTION STRUCTURE IN APPARENT THICKENING BEHAVIOR OF DILUTE PEO/WATER SYSTEMS.** An experimental investigation was undertaken to determine the role of solution structure on the apparent thickening behavior exhibited by 'dilute' polyethylene oxide/water solutions in extensional flow. As the wall shear rate was increased, slightly shear thinning behavior was observed up until a critical wall shear rate was exceeded at which point a large increase in relative viscosity was seen. Other researchers have observed these apparent thickening effects and have interpreted them in terms of individual polymer molecules undergoing coil-stretch transitions. However, in the systems used in this study, the critical wall shear rate and the degree to which relative viscosity increased were both seen to be strong functions of solution aging time and concentration. These results are inconsistent with the simple picture of individual polymer coils undergoing a coil-stretch transition and instead are consistent with the picture of aggregated systems or microneetworks being stretched from their equilibrium configurations. (Edited author abstract) 28 refs.

**082789 DIELECTRIC RELAXATION IN DILUTE**

**SOLUTIONS OF POLY(ORGANOPHOSPHAZENES): EVIDENCE OF THE LOCALIZED ELECTRONIC STRUCTURE OF THE P=N DOUBLE BONDS.** Dielectric measurements were carried out on dilute benzene solutions of fractionated poly(diphenoxyphosphazene) at a concentration of ca. 0.1%. Loss maxima were observed in the audiofrequency range at 303 K. The relaxation times  $\tau$  determined from the frequencies of these loss maxima increased with increasing (weight-average) molecular weight  $M_w$  of the fractions in proportion to  $M_w^{1.7}$ . This molecular weight dependence and the absolute values of  $\tau$  were in agreement with the prediction of the Zimm theory evaluated by using the experimental intrinsic viscosity values. Thus, poly(phosphazene) can be classified as a type A polymer which has components of the moment aligned in the same direction parallel to the chain contour. (Edited author abstract) 18 refs.

**082792 UBIQUITY OF STRETCHED-EXPONENTIAL FORMS IN POLYMER DYNAMICS.** Literature results on the zero-shear viscosity  $\eta$ , rotational diffusion coefficient  $D_R$ , and sedimentation coefficient  $s$  of polymers in good,  $\Theta$ , and marginal solvents are reanalyzed in terms of the universal scaling equation  $A = A_0 \exp(-ac^v)$ , where  $A$  is a transport coefficient,  $c$  is the polymer concentration, and  $a$  and  $v$  are scaling constants. This equation gives reasonably good descriptions of almost all results on  $\eta$ ,  $D_R$ , and  $s$ , a single pair of parameters ( $a, v$ ) sufficing for results from all concentrations. There is apparently no qualitative change in transport behavior between the dilute and semidilute regimes. (Author abstract) 37 refs.

Phillips, George D.J. (Worcester Polytechnic Inst, Worcester, MA, USA); Peczak, Pavel. *Macromolecules* v 21 n 1 Jan 1988 p 214-220.

**082793 ENTANGLEMENTS IN POLYMER SOLUTIONS UNDER ELONGATIONAL FLOW: A COMBINED STUDY OF CHAIN STRETCHING, FLOW VELOCIMETRY, AND ELONGATIONAL VISCOSITY.** The progressive development of entanglements can be detected by observing strain patterns during increasing elongational strain rate where each stage is attributable to a transient network with a lifetime appropriate to the corresponding strain rate. The flow velocities are affected locally by transient network stretching, and this has pronounced influence on the macroscopic flow resistance (elongational viscosity). The latter should be highly relevant to the interpretation of continuum hydrodynamics of polymer solutions within elongational flow fields in terms of molecular behavior. This work shows that this will only be possible by taking account of the 'microstructure' in molecular strain and in the correspondingly

modified flow velocities, arising as a consequence of the long relaxation times associated with the stretching of transient networks. (Edited author abstract) 17 refs.

Chow, A. (Univ of Bristol, Bristol, Engl); Keller, A.; Mueller, A.J.; Odell, J.A. *Macromolecules* v 21 n 1 Jan 1988 p 250-256.

**082794 VISCOSITY OF POLY(HEXAZOCYCLANE) SOLUTIONS.** Viscosity of poly(hexazocyclanes) was measured in a non-protonic (N-methylpyrrolidone) and a protic solvent (formic acid). In amidic solvents poly(hexazocyclanes) form metastable aggregates and their solutions are in a transition state to colloid systems. In formic acid they dissolve molecularly; viscosity in this solvent is higher than in N-methylpyrrolidone by a factor of 2.5 to 3, and increases upon dilution (polyelectrolyte effect). Gelation sets in at concentrations above 10 to 15%. It is shown that one of the main reasons for the formation of aggregates in N-methylpyrrolidone is apparently a negligible polymer-solvent interaction, given by the chemical structure of the studied polymers. The properties of polymer solutions change very markedly when the macromolecules contain amidic groups which bring about substantial intermolecular interaction between the polymer and the solvent. (Edited author abstract) 9 refs.

**082795 ENTROPY OF INHOMOGENEOUS POLYMER-SOLVENT SYSTEMS.** The entropy of inhomogeneous polymer solutions has been evaluated using a lattice model. Previous models for polymer solutions considered only the enthalpic contributions, and a more complete expression for the free energy is obtained by adding the entropic term. The resulting expression is used to predict the characteristics of spinodal decomposition of polymer solutions and the interfacial tension between demixed polymer solutions. There is general improvement in the agreement between theory and experiment when the entropic effects are included. (Author abstract) 14 refs.

**082797 DIMENSIONS OF A POLYMER CHAIN IN A MIXED SOLVENT.** The equilibrium behavior of a flexible polymer in a binary solvent mixture is investigated via Monte Carlo simulation. The mixed solvent is molded as an Ising fluid occupying the sites of a simple cubic lattice, with the polymer described as a self-avoiding random walk on the same lattice. The solvent has a critical consolute point, and the polymer preferentially adsorbs the better solvent component. A coupling between preferential adsorption and the solvent correlations present near the consolute temperature of the solvent causes the chain to contract, as predicted by F. Brochard and P.-G. de Gennes. However, preferential adsorption, also causes chain contraction far from the critical temperature. At

large values of preferential adsorption, the chain contracts below the dimensions it would have in either of the pure solvent components. (Author abstract) 29 refs.

**082798 PHASE SEPARATION IN TERNARY SYSTEMS SOLVENT-POLYMER 1-POLYMER 2, 3. HOMOGENEOUS DOUBLE CRITICAL POINTS.** A number of quantitative relations have been developed for homogeneous double critical points (HODCP's) in Flory-Huggins ternary systems solvent-polymer 1-polymer 2 with interactions characterized by polymer-polymer parameter  $g_1$  and solvent-polymer parameters  $g_1$  and  $g_2$ . Their location in the composition diagram is restricted to three linear segments, and they can exist only for combinations of  $g_1$  and  $\Delta g$  ( $\Delta g \equiv g_2 - g_1$ ) limited to double-sector areas of the  $g_1$ ,  $\Delta g$  plane. The lower sectors contain exclusively elliptic HODCP's marking disappearance of closed-loop binodals, while the upper sectors are divided between hyperbolic (marking confluence of two binodal regions) and unstable elliptic types. Sector vertices represent unique systems where the effect of unequal chain lengths is just balanced by interactions to produce a constant critical temperature, independent of composition. Conditions for multiple occurrence of HODCP's and relations for orientation of spinodals at HODCP's are derived. (Author abstract) 10 refs.

**082799 DIFFUSION-LIMITED PHOSPHORESCENCE QUENCHING INTERACTIONS IN POLYMER SOLUTIONS: SMALL MOLECULE-SMALL MOLECULE INTERACTIONS INTERPRETED BY FREE VOLUME THEORY.** Diffusion-limited interactions between benzil and anthracene were studied by phosphorescence quenching in polystyrene-cyclohexane, polystyrene-toluene, poly(methyl methacrylate)-toluene, and poly(butadiene-cyclohexane) solutions. Values of the bimolecular diffusion-limited quenching rate constant,  $k_q$ , were obtained by measuring benzil phosphorescence lifetime as a function of anthracene concentration and applying a Stern-Volmer analysis. Besides polymer species and solvent,  $k_q$  was measured as a function of polymer molecular weight and concentration, up to 560 g/L.  $k_q$  was found to be independent of polymer molecular weight in polystyrene-cyclohexane solutions and exhibited a slight molecular weight dependence in polystyrene-toluene solutions. (Edited author abstract) 52 refs.

**082800 CHAIN CONFORMATION IN TERNARY POLYMER SOLUTIONS.** This paper presents a theoretical study on chain conformation of a solute polymer P in a mixture of different chemical species A and B, where A is a good solvent and B is a nonsolvent or an incompatible polymer. In the case of B being a nonsolvent, particular attention is drawn in the vicinity of the critical point of the A/B solvent mixture. On the basis of a lattice theory extended to inhomogeneous three-component polymer systems, it is found that the polymer chain P is swollen in the concentration region close to the critical demixing point. We present quantitative calculation and compare it with the experimental results obtained for the poly(tetrahydrofuran)/methanol/cyclohexane system. (Edited author abstract) 21 refs.

**082801 BEAD-SPRING MODEL PREDICTIONS OF SOLUTION DYNAMICS FOR FLEXIBLE HOMOPOLYMERS INCORPORATING LONG-CHAIN BRANCHES AND/OR RINGS.** A generalization of the model of Zimm is presented which predicts solution

dynamics for chains composed of any assortment of identical spherical beads connected by identical Hookean springs. The model is formulated in a coordinate system that translates with the chain to ensure that the predicted dynamic properties may be computed, regardless of chain size or degree of hydrodynamic interaction, with the efficient eigenvalue algorithm applied by A.S. Lodge and Y. Wu to linear chains. Several new block-diagonal matrices, which further improve the computation efficiency for linear ring, and regular H structures, also arise from this formulation. (Edited author abstract) 32 refs.

**082802 ON THE APPARENT RADIUS OF GYRATION OF LINEAR POLYMERS AND THE EXPERIMENTAL DETERMINATION OF THE EXCLUDED-VOLUME PARAMETER.** The structure factor for linear polymers in the  $\Theta$  state is given by the well-known Debye function. In a good solvent the chain is subject to excluded volume; however, the form of the structure factor still closely resembles that of the Debye function. As a result, one is tempted to interpret the structure factor as a Debye function whose argument is scaled by the radius of gyration of the swollen chain. We present here rigorous and numerical arguments which demonstrate that such an interpretation is legitimate only for small values of the argument. An asymptotic expression for the structure factor suggests a method of measuring the value of the excluded-volume variable  $Z$  by experiment. (Author abstract) 16 refs.

**082803 DEMIXING OF AQUEOUS POLYMER TWO-PHASE SYSTEMS IN LOW GRAVITY.** When polymers such as dextran and poly(ethylene glycol) are mixed in aqueous solution, biphasic systems often form. On Earth the emulsion formed by mixing the phases rapidly demixes because of phase density differences. Biological materials can be purified by selective partitioning between the phases. In the case of cells and other particulates the efficiency of these separations appears to be compromised by the demixing process. To modify this process and to evaluate the potential of two-phase partitioning in space, experiments on the effects of gravity on phase emulsion demixing were undertaken. Results indicate that demixing can occur rather rapidly in space, although more slowly than on Earth. We have examined the demixing process from a theoretical standpoint by applying the theory of Ostwald ripening. (Edited author abstract) 38 refs.

**082804 LASER-DOPPLER MEASUREMENTS OF TURBULENCE STRUCTURE IN A DRAG-REDUCING PIPE FLOW WITH POLYMER INJECTION.** Aqueous solutions of polyethylene oxide were injected into a pipe flow through a small tube at the center of a pipe. The turbulent characteristics in drag-reducing flow with polymer injection were measured by means of a Laser Doppler Velocimeter (LDV). The experimental results were compared with measurements both in a Newtonian fluid (water) flow and in a premixed flow with 300 ppm homogeneous polymer solution. The experimental results suggested that the polymer injection caused a thickening of the buffer layer, enlargement of macroscale turbulent eddy and suppression of fine turbulent eddy. A difference in turbulent characteristics between premixed and polymer injected systems was observed in the distributions of turbulent macroscale, skewness factor and flatness factor. (Edited author abstract) 17 refs.

**082805 SURFACE INTERACTIONS IN COMPATIBLE POLYMER (AND BLOCK COPOLYMER) SOLUTIONS.** We study theoretically the effects of competing surface interactions in a system of two miscible polymers (A and B) in a good solvent, using the self-consistent mean-field formulation with ground-state dominance, as is appropriate to moderately concentrated systems. We take the A chains to be attracted to the surface and the B chains to be repelled. From susceptibility arguments, one expects a wide A-rich zone to appear at the surface, close enough to the A-B demixing transition. This (and several other qualitative expectations) is confirmed by explicit numerical and analytic calculations of (1) concentration profiles and (2) interfacial energies, for various values of the excluded volume parameters and bulk concentrations. (Edited author abstract) 19 refs.

**082806 RANDOMLY BRANCHED POLYMERS: SEMIDILUTE SOLUTIONS.** We study the conformation of randomly branched polydisperse polymers in semidilute solutions. Starting from the dilute case, when the different macromolecules are far apart from each other, we suggest that above a concentration  $C^*$ , where the polymers come into contact, a semidilute regime occurs. In this regime, one may separate the distribution of molecular weights into two parts. The smaller molecules behave as in the dilute regime. They penetrate the larger ones and screen out the excluded-volume interaction. Thus large polymers behave as in the reaction bath. (Edited author abstract) 25 refs.

**082807 PREDICTION OF SOLVENT ACTIVITIES IN POLYMER SOLUTIONS USING AN EMPIRICAL FREE VOLUME CORRECTION.** A recent correlation for solvent activities in polymer solutions is extended in scope to provide a methodology for modeling nonideal effects in polymer solutions. This new method allows the use of any expression for the residual (enthalpic) interaction between polymer and solvent in conjunction with a standard (Flory-Huggins) expression for the combinatorial entropy. An empirical free volume correction uses the infinite dilution weight fraction activity coefficient of the solvent as an adjustable parameter. The new method is applied using one residual term given by the analytical solution of groups (ASOG) technique, one similar to the Flory-Huggins interaction term, and one which yields no residual interaction. (Edited author abstract) 23 refs.

**082809 INFLUENCE OF PRESSURE ON THE TRANSITION PHENOMENON IN DILUTED SOLUTIONS OF POLY(DIACETYLENES).** Hydrostatic pressure in the range from 1 to 3400 bar induces the

transition phenomenon in diluted solutions of polydiacetylenes. With respect to the influence of pressure on the absorption bands, the transition was studied by UV spectroscopy. The transition is shown to depend strongly on the hydrogen bonds between the sidegroups. In the case of P-DDD which is free of H-bonds, the temperature and pressure effect on the transition is first-order-like in that temperature range where no precipitation occurs. Transient processes, except those involving precipitated particles, occur below the experimental time scale of minutes. In P-4BCMU, a polydiacetylene with H-bonds between the sidegroups, the pressure-induced isothermal transient phenomena are slowed down, and exhibit a nonexponential time law. **082810 DIFFUSION PERMEABILITY IN CONCENTRATED POLYMER SOLUTIONS: THE FLUORESCIN-DEXTRAN-WATER SYSTEM.** The diffusion of fluorescein as a dilute solute in more concentrated (matrix) solutions of sucrose, raffinose, different fractions of dextran in a molecular weight range from 1000 to 500,000 and Ficoll has been measured as a function of matrix concentration over an extended interval (2.5-20% w/w matrix). The presence of a macromolecule at 20% w/w could reduce the diffusion rate between four and five times. At small molecular weights the effect was less pronounced. (Edited author abstract) 4 refs.

**082812 LATTICE MODELS OF BRANCHED POLYMERS: DYNAMICS OF UNIFORM STARS.** We report exact enumeration and Monte Carlo results on the dynamics of uniform star polymers. The treatment is at the level of the Zimm rigid body approximation and we use a lattice model incorporating the effects of excluded volume. We have calculated the sedimentation velocity and intrinsic viscosity, and hence the hydrodynamic radius, as a function of the number of branches in the star and the number of monomers in each branch. We have varied the bare friction by changing the effective bead radius ( $a$ ) and we discuss the sensitivity of the results to the value of  $a$ . We compare our results, for appropriate ratios of quantities for branched and linear polymers, with those of other theoretical treatments and with experimental results. (Author abstract) 26 refs.

**082813 COMPARISON OF DIFFUSION COEFFICIENTS IN TERNARY POLYMER SOLUTIONS MEASURED BY DYNAMIC LIGHT SCATTERING AND FORCED RAYLEIGH SCATTERING.** In this work we report further measurements of PS diffusion in Poly(Vinyl Methyl Ether) (PVME) solutions, by both Dynamic Light Scattering (DLS) and forced Rayleigh scattering (FRS), as a function of matrix concentration. In

addition, as fixed PVME concentrations the DLS measurements have been repeated as a function of PS concentration. The main conclusion from the experimental results is that the magnitude of  $k_D$  in ternary solutions is less than or equal to that in pure solvent, and no substantial error is incurred by equating  $D_{meas}$  and  $D_r$ . A remarkable feature of these data is that the transition from good to apparently  $\theta$ -like quality occurs at very low PVME concentrations. 32 refs.

**082814 PHOTOSENSITIVE POLYMERS. PHOTOSTIMULATED VISCOSITY CHANGE OF POLY(3-VINYL-10-METHYLPHENOTHIAZINE) IN 1,2-DICHLOROETHANE IN THE PRESENCE OF CARBON TETRACHLORIDE.** The solution viscosity of poly(3-vinyl-10-methylphenothiazine) in 1,2-dichloroethane was found to decrease by as much as 50 percent on exposure to ultraviolet light in the presence of carbon tetrachloride. The reduced viscosity again returned to the initial value by the addition of reductants, such as sodium dithionite. Absorption and ESR measurements of the solution suggested the formation of radical cations of pendant methylphenothiazine (MPT) groups by the interaction of the photoexcited MPT with carbon tetrachloride. Aggregation of ion-pairs of the cations and chloride ions due to dipole-dipole interactions is considered to be the driving force of the chain contraction. The addition of sodium dithionite reduces the radical cations to neutral forms and the chain again returns to the initial random conformation. (Author abstract). 8 Refs.

**082815 CARBON-13 NMR INVESTIGATION OF LOCAL DYNAMICS IN BULK POLYMERS AT TEMPERATURES WELL ABOVE THE GLASS TRANSITION TEMPERATURE. 1. POLY(VINYL METHYL ETHER).** Carbon-13 spin-lattice relaxation time determinations have been performed on poly(vinyl methyl ether) in solution and in bulk above the glass transition temperature. The high experimental value of the minimum of  $T_1$  as a function of temperature cannot be accounted for by the specific orientation autocorrelation functions for polymers. The authors postulate the existence of an additional fast anisotropic motion, which they have assigned to librations of limited extent of the internuclear CH vectors about their rest position. Comparison of solution and bulk data has established that molecular motions of poly(vinyl methyl ether) are of the same nature in solution and in bulk at temperatures above  $T_g$ . **082816 PARTIAL DRAINING AND UNIVERSALITY OF DILUTE SOLUTION POLYMER DYNAMICS: COMPARISON OF THEORY AND EXPERIMENT.** Previous renormalization group calculations predict that the conventional Flory ratios  $P/P_0$  and  $\Phi/\Phi_0$  are not universal functions of excluded volume alone in dilute solutions because of a partial draining effect (finite hydrodynamic interactions) that splits the scaling functions into a family of curves. The theory also predicts that the ratio presented is almost independent of draining and is more nearly a universal function of excluded volume (i.e., the expansion factor  $a_3$ ). These predictions are tested against experimental data for polystyrene, poly( $\alpha$ -methylstyrene), and polyisobutylene, a sequence that is interpreted as having increasing relative nondraining behavior. Procedures are outlined for more quantitative tests of the theory. (Edited author abstract). 39 Refs.

**082817 ISOTROPIC-LIQUID CRYSTAL PHASE**

**EQUILIBRIUM IN SOLUTIONS OF SEMIFLEXIBLE POLYMERS: POLY(HEXYL ISOCYANATE).** The isotropic-liquid crystal phase equilibrium was investigated for solutions of poly(hexyl isocyanate) (PHIC) in toluene and dichloromethane. Substantially monodisperse samples were used to determine the dependence of the phase diagram on molecular weight, temperature, and solvent. The determined molecular weight dependence greatly differed from the prediction of the theories of L. Onsager and of P.J. Flory for rigid rods. This was attributed to the flexibility of PHIC characterized by the persistence length  $q$  of 21-41 nm in these solvents. The data for the solutions of PHIC in toluene, together with those for aqueous schizophyllan (a triple helical polysaccharide,  $q=200$  nm), were compared almost quantitatively with the prediction of the theory of A.R. Khokhlov and A.N. Semenov for wormlike cylinders with hard-core repulsive potential. (Edited author abstract). 37 Refs.

**082818 RELAXATION TIMES OF POLYMER SOLUTION IN THE SEMIDILUTE REGION FOR ZERO-SHEAR VISCOSITY.** Relaxation times  $\tau_w$  and  $\tau_0$  of polymer solutions in the semidilute region for the zero-shear viscosity  $\eta'$  were studied in good and  $\Theta$  solvents. Here,  $\tau_w$  is the weight-average relaxation time evaluated from the product of  $\eta'$  and the steady-state compliance  $J_e$ , and  $\tau_0$  is the relaxation time specifying shear rate dependence of viscosity. It is found that  $\tau_0$  is proportional to  $\tau_w$  regardless of concentration and solvent power, and the concentration and molecular weight dependences of both relaxation times can be well understood if the semidilute region for  $\eta'$  is divided into two regions, i.e., the dilute and entangled regions for  $J_e$ . **082819 EXTENDED UNIVERSAL COEXISTENCE CURVE FOR POLYMER SOLUTIONS.** The symmetrized universal coexistence (COEX) curve for binary polymer/solvent solutions, as proposed by I.C. Sanchez has been extended based on the Wegner expansion. Together with empirical relationships between the polymer molecular weight ( $M$ ) and the critical volume fraction as well as between  $M$  and the critical solution temperature, all the high-precision COEX curve data for polystyrene (PS) in methylcyclohexane (MCH) and in cyclohexane (CH) can be represented by an expression that is presented by the authors. Results of the extended universal COEX curve permit us to distinguish phase-separation behavior from polymer coil-to-globule transition. (Edited author abstract). 15 Refs.

**082820 NEWTONIAN VISCOSITY OF POLYMER SOLUTIONS.** Viscosity measurements of cellulose acetate and polyisobutylene over a wide range of concentrations and molecular weights have been made. The data so obtained and the data taken from literature for schizophyllan show that the viscosity varies smoothly with the concentration of the polymer for the whole range of concentrations and molecular weights investigated. The characteristic concentrations,  $c_{ch}$ , of the polymers are calculated by the following equations:  $c_{ch}=0.77/[\eta]$  or  $c_{ch}=1.08/[\eta]$ . The relationship between molecular weight and intrinsic viscosity is obtained by fitting the data by the method of least squares. (Edited author abstract). 20 Refs.

**082821 LIQUID CRYSTALLINE STRUCTURE OF SOLUTIONS OF POLY- $\gamma$ -BENZYL-L-GLUTAMATE.** Over a wide interval of change in concentrations, temperature and MM (Molecular Mass) from the texture of the 'fingerprints' the authors have determined the pitch of the cholesteric helix P for LC solutions of poly- $\gamma$ -benzyl-L-glutamate in DMFA. The experimentally obtained dependences of the pitch of the cholesteric helix on temperature, concentration and MM are discussed in relation to various theories. In relation to the kinetic approach, an explanation offered for the experimentally discovered maximum in the dependence of the pitch on MM according to which non-monotonic change in pitch is a consequence of change in the form of the molecule with increase in its contour length to a value equal to and beyond the persistent length. (Edited author abstract). 21 Refs.

**082823 SPIN-COATING PROCESS MECHANISM RELATED TO POLYMER SOLUTION PROPERTIES.** Coating the substrate with an amorphous polymer layer is a very common process in the manufacturing of integrated circuits, but the fundamental spin-coating mechanism has not yet been precisely determined. This study examines the influence of the macromolecular characteristics on the spin-coating process both experimentally and from a phenomenological point of view. It is concluded that the weight-average molecular weight of the spun-on solution is a pertinent parameter, and that chain entanglements in polymer solutions may be considered as the basic phenomenon responsible for the formation of the solid polymer layer. (Author abstract). 17 Refs.

**082827 THERMODYNAMIC MODEL FOR TWO-PHASE AQUEOUS POLYMER SYSTEMS.** The main objective of this work is the development of a predictive model for the liquid-liquid equilibrium of aqueous solutions containing two chemically different polymers. The authors show that this can be done by using the UNIQUAC model with the interaction parameters for the water-dextran and water PEG systems obtained from osmotic pressure data for these binary aqueous polymer solutions, and by fixing the dextran PEG parameters, or almost as well as using the parameters reported here in the absence of osmotic pressure data. It is shown that the UNIQUAC model leads to predictions of better accuracy than the Flory-Huggins model and, indeed, the predictive (zero-parameter) UNIQUAC model is almost as accurate as the correlative (three-parameter) Flory-Huggins model. This work is pertinent to liquid extraction processes involving biological materials. 18 Refs.

**082828 ENHANCEMENT OF ENERGY TRANSFER BETWEEN DYE SOLUBILIZATES IN A POLYMER/SURFACTANT COLLOID SYSTEM.** Energy transfer from excited proflavine (PF) to rhodamine 6G (R6G) was measured in sodium dextran sulfate/dodecyltrimethylammonium bromide mixed solutions by monitoring both the quenching of PF emission and the enhancement of R6G emission as a function of concentrations of surfactant and acceptor. A strong correlation was observed between the quenching of donor emission and the enhancement of acceptor emission. Remarkable enhancement of energy transfer was found in polyion/surfactant mixed solution, while no or very little energy transfer was observed in the polyion solution in the absence of surfactant. This enhancement of energy transfer is attributed to the solubilization of the donor/acceptor dye pair in monomeric form into a surfactant cluster bound in the polyion domain. (Author abstract) 26 refs.

**082829 SYNTHESIS AND SOME SPECTROSCOPIC PROPERTIES OF POLYANIONS WITH PENDANT MERCOCYANINE DYES.** Polymers tagged with a local pH reporter were synthesized. A methacrylate-type monomer containing a merocyanine dye residue as a reporter dye was synthesized. Its homopolymer and copolymers with sodium 2-acrylamido-2-methylpropane-sulfonate were prepared by free radical polymerization. These polymers showed a characteristic color change in aqueous solutions from yellow to red with increasing pH from acidic to basic conditions according to the acid-base equilibria of the merocyanine dye residues. Since the electrostatic potential and polarity of media have a strong effect on the acid-base equilibria, the pendant merocyanine residues are expected to serve as a reporter to provide information on the local environments around the polymer chain at which the dye molecules are incorporated. **082832 TWO-DIMENSIONAL MAS NMR: NEW PROSPECTS FOR THE INVESTIGATION OF PARTIALLY ORIENTED POLYMERS.** Single crystals are difficult if not impossible to obtain. Examples are synthetic liquid crystalline and biological polymers. Often such materials can, however, be partially oriented. If a set of rotor-synchronized <sup>13</sup>C MAS NMR spectra is taken of a macroscopically anisotropic sample for different initial rotor phases, a two-dimensional sideband spectrum can be generated by a subsequent second Fourier transformation over the rotor phase. From the sideband intensities in the

new dimension the orientational distribution function can be derived for the individual carbon positions. The method is reviewed and demonstrated on samples of liquid crystalline polymers and drawn polyethylene terephthalate. (Edited author abstract) 15 refs.

**082833 SPECTROELECTROCHEMICAL STUDIES OF ELECTROCHEMICALLY PREPARED POLY-3-METHYLTHIOPHENE.** Electrochemically prepared poly-3-methylthiophene has been characterized employing spectroelectrochemical techniques. Results indicate that both oxidized and reduced forms of the polymer are stoichiometrically stable and the doping process is chemically reversible. The anodic doping level is between 0.12 to approx. 0.19 as determined from spectroelectrochemical measurements, and several different functional groups appear to undergo redox reactions. (Author abstract) 21 refs.

**082834 CHARACTERIZATION OF NEUTRAL SOLITON DYNAMICS IN PRISTINE TRANS-POLYACETYLENE BY MEANS OF ANISOTROPIC ESR T<sub>1</sub> AND LINE WIDTH.** Anisotropy patterns for ESR T<sub>1</sub> and line width at 300K and at 50, 500 MHz and X-band were reported. Phases and frequency dependences of all patterns were understood by rapid 1-D diffusion of neutral solitons, except for line width of t-(CH)<sub>x</sub>, which could be reasonably interpreted by the trapping effect. This result means that in analysis on the neutral soliton dynamics, effects by trapping should be taken into account. (Author abstract) 14 refs.

**082835 TWO-DIMENSIONAL <sup>1</sup>H AND <sup>13</sup>C NUCLEAR MAGNETIC RESONANCE STUDIES OF POLY(VINYL ALCOHOL).** The <sup>1</sup>H and <sup>13</sup>C nuclear magnetic resonance spectra of atactic poly(vinyl alcohol) in D<sub>2</sub>O at a temperature of 353 K were analyzed by various two-dimensional NMR (2D NMR) methods including <sup>1</sup>H J-resolved spectroscopy, <sup>1</sup>H F<sub>1</sub>-axis broad-band decoupled correlation spectroscopy, <sup>1</sup>H broad-band decoupled <sup>13</sup>C-<sup>1</sup>H chemical shift correlation spectroscopy, and two-dimensional INADEQUATE spectroscopy. The combined use of these two-dimensional NMR methods provided absolute assignments of <sup>1</sup>H and <sup>13</sup>C spectra at triad-tetrad and pentad-hexad levels, respectively. The polymerization of PVA follows Bernoulli statistics with P<sub>nn</sub> = 0.47 at the triad-tetrad level, but does not follow any statistics at the pentad-hexad level. (Author abstract) 33 refs.

**082836 LASER DESORPTION FOURIER TRANSFORM MASS SPECTROMETRY OF POLYMERS: COMPARISON WITH SECONDARY ION AND FAST ATOM BOMBARDMENT MASS SPECTROMETRY.** A series of alkoxyated pyrazole and hydrazine polymers with average molecular weights between 600 and 1300 were studied by using laser desorption Fourier transform mass spectrometry. Spectra primarily contain +• and Na<sup>+</sup>-attached intact oligomer ions and show little evidence of fragmentation. LD-FTMS spectra are compared with previously reported secondary ion and fast atom bombardment spectra of the same polymers. In general, laser desorption spectra show more regular polymer distributions, fewer fragment ions, and less mass discrimination. (Author abstract) 9 refs.

**082837 NUCLEAR MAGNETIC RESONANCE STUDY OF POLY(ARYL ETHER ETHER KETONE).** Amorphous and crystalline samples of poly(aryl ether ether ketone) have been studied in the solid state by both <sup>13</sup>C high-resolution cross-polarization/magic-angle spinning (CP/MAS) nuclear magnetic resonance (nmr) and wide-line <sup>1</sup>H nmr. The <sup>13</sup>C spectrum was assigned using the dipolar dephased and variable-contact-time experiments. The CP/MAS spectrum of the amorphous sample displays much broader signals than does the crystalline sample. The <sup>1</sup>H wide-line spectra were measured at temperatures from 295 to 440 K. The <sup>1</sup>H spectra appeared as two superimposed signals having different spin-lattice relaxation times. At all temperatures below the glass transition, the lines of the crystalline spectra were wider and showed longer spin-lattice relaxation times than those of the amorphous spectra. (Author abstract) 24 refs.

**082838 E.S.R. OF BF<sub>4</sub><sup>-</sup>-DOPED POLYTHIOPHENE.** We have studied poly(3-methylthiophene) doped electrochemically with BF<sub>4</sub><sup>-</sup> by electron spin resonance. The spin concentration increases linearly by about one spin per injected charge up to quite high doping levels (about 10 mol% at room temperature). The magnetic susceptibility χ<sub>m</sub>(T) gradually changes from a Curie to a Pauli-type behavior with increasing doping concentration. The results demonstrate that polarons are the dominant charge states in poly(3-methylthiophene) doped with BF<sub>4</sub><sup>-</sup>. (Edited author abstract) 26 refs.

**082839 ELECTRON ENERGY LOSS SPECTROSCOPY: APPLICATION TO SYNTHETIC ORGANIC POLYMERS.** Electron energy loss spectroscopy has been examined as a possible tool for measuring the atomic composition of polymers on a local scale in the transmission electron microscope. Thin films of nylon 6,6 and single crystal lamellae of poly(chlorotrifluoroethylene) were investigated as model systems. Spectra were obtained using a 100 kv electron beam. Results for nylon 6,6 gave fairly good quantitative agreement between the measured relative atomic contents of carbon, nitrogen, and oxygen (77, 9 and 14%, ±5%, respectively) and the calculated values (75, 12.5, and 12.5%, respectively). Spectra obtained for poly(chlorotrifluoroethylene) single crystals revealed significant mass loss of chlorine as a function of electron dose. (Edited author abstract) 25 refs.

**082840 DIRECT PYROLYSIS MASS SPECTROMETRY OF CHLORINE-CONTAINING POLYMERS USING CAPILLARY GC/MS.** A direct pyrolysis mass spectrometric technique has been developed and applied to several chlorine-containing polymers. The capillary column in the gas chromatograph has been replaced by uncoated fused silica tubing to avoid the problem of column degradation induced by the polymer pyrolyzates. Under appropriate conditions, the pyrolysis mass spectra were found to be highly reproducible and to serve as 'fingerprints'. The technique can be readily applied to carbon-black-filled, crosslinked elastomers, as well as polyblends and composites. The quantitative aspects of the technique have also been addressed. (Author abstract) 16 refs.

McGuire, Jeffrey M. (Hercules Inc Research Cent, Wilmington, DE, USA); Bryden, Charles C. *J Appl Polym Sci* v 35 n 2 Feb 5 1988 p 537-548.

**082841 <sup>29</sup>Si NUCLEAR MAGNETIC RESONANCE OF DIMETHYL AND PHENYLMETHYL CONTAINING POLYSILANES.** The <sup>29</sup>Si-NMR spectra are reported for poly(methylphenylsilylene) (1), poly(1,1,2-trimethyl-2-phenyldisilene) (2), two samples of poly-

dimethylsilylene-co-phenylmethylsilylene) (3a) and (3b), and poly(phenylmethylsilylene-co-n-hexylmethylsilylene) (4). The spectra of 3a, 3b, and 4 indicate that these polymers contain blocklike regions with considerable segregation of RMeSi and PhMeSi groups. The spectrum of 2 shows no evidence for stereospecific or regiospecific polymerization. The preparation of 2 from 1,1,2-trimethyl-2-phenyldichlorosilane is also described. (Author abstract) 16 refs.

Wolff, Andrew R. (Univ of Wisconsin, Madison, WI, USA); Nozue, Ikuo; Maxka, Jim; West, Robert. *J Polym Sci Part A* v 26 n 3 Mar 1988 p 701-712.

**082842 <sup>29</sup>Si NUCLEAR MAGNETIC RESONANCE OF DIALKYLPOLYSILANES.** The silicon-29 nuclear magnetic resonance spectra of a number of dialkyl- and alkylmethylpolysilanes are reported. Polysilanes composed of asymmetrically substituted silylenes (i.e., alkylmethylsilylenes) exhibited very broad resonance lines attributed to diastereomeric chemical shifts of stereogenic silylenes alpha and beta to the observed nucleus. Symmetrically substituted polysilanes showed a single narrow peak. The <sup>29</sup>Si chemical shifts for these polysilanes decrease with increasing steric bulk of the substituents, varying inversely with the electronic excitation energy. (Author abstract) 18 refs.

**082843 ANALYSIS OF POLYMER SURFACES BY SIMS: 12. ON THE FRAGMENTATION OF ACRYLIC AND METHACRYLIC HOMOPOLYMERS AND THE INTERPRETATION OF THEIR POSITIVE AND NEGATIVE ION SPECTRA.** The positive and negative ion spectra from homologous series of alkyl methacrylate, hydroxyalkyl methacrylate and alkyl acrylate polymers; poly(methacrylic acid) and poly(methacrylic anhydride) are reported. A systematic interpretation of the spectra can be accomplished on the basis of fragmentation pathways consistent with the known effects of other ionizing radiations. The negative ion spectra, previously little studied, are a powerful probe of structure for this class of polymer. (Author abstract) 14 refs.

Hearn, M.J. (ICI PLC, Middlesbrough, Engl); Briggs, D. *Surf Interface Anal* v 11 n 4 Feb 1988 p 198-213.

**082844 APPLICATION OF FIELD DESORPTION MASS SPECTROMETRY TO POLYMER AND OLIGOMER ANALYSIS.** This review discusses the application of field desorption mass spectrometry (FDMS) to the determination of molecular weight distributions, the characterization of oligomer mixtures, the analysis of the reaction mechanism of styrene, and the analysis of thermal behavior. It is demonstrated that FDMS is effective for the analysis of polymers or oligomers, allowing the determination of molecular weight distributions, the characterization of oligomeric mixtures, and the analysis of reaction mechanisms and thermal behaviors in polymeric or oligomeric systems. However, this method has some drawbacks. Hence, for example, since FDMS only provides one item of information (the molecular ion), it is incapable of distinguishing isomers that may coexist in the system and is incapable of deducing their structures. Secondly, FDMS is not applicable to polymers with molar masses greater than 10,000 daltons. Thirdly, the fact that FDMS is compound-selective provides some problems, since desorption rates and ionization efficiencies depend quite closely on molecular weight, volatility, chemical structure, and similar factors. Nevertheless, despite these difficulties, FDMS has been applied to various fields of polymer analysis, and has provided a complement to structural data obtained by IR and NMR spectroscopy. 44 refs.

**082845 FACTORS AFFECTING THE SAMPLING OF POLY(ETHYLENIMINES) BY ELECTROHYDRODYNAMIC MASS SPECTROMETRY.** The effects of polymer structure and solution chemistry on sampling by electrodynamical (EH) mass spectrometry were studied by using poly(ethylenimines) (PEIs). In contrast with results for poly(ethylene glycols), number average molecular weight calculated from desorption ionization mass spectra of PEIs are generally too low, with the discrepancy becoming greater with increasing molecular weight. The effects of adding acid and transition-metal ions indicate that sampling bias in EH mass spectrometry is in part due to strong solvent-ion interactions resulting from poor shielding of charge sites in multiply charged adducts, with a contribution from hydrogen bonding interactions between polymer and solvent. (Edited author abstract) 40 refs.

**082846 MOTION OF JUNCTION POINT IN NETWORK SYSTEMS BY  $^{31}\text{P}$ -NMR LINESHAPES AND RELAXATION.** Advances in magnetic resonance techniques over the past ten years have made accessible many details of insoluble systems. In favorable cases it was possible to delineate some specific molecular interactions and motions. The authors have performed  $^{13}\text{C}$  MAS-CP NMR studies on a number of network polymers derived from  $\alpha$ ,  $\omega$ -dihydroxy poly(propylene oxide) MW=400, 1000, 2000, 3000, or 4000 crosslinked with tris(4-isocyanatophenyl)thiophosphate. They began these studies with the intention of characterizing both spatial and time parameters of the junction point motion as a function of  $M_c$ , the molecular weight between crosslinks. This preliminary report shows that  $^{31}\text{P}$ -NMR is acutely sensitive to details of motion of the junction and that the resultant powder patterns and relaxation times can be used to greatly extend our knowledge of junction point constraints. The results shown here clearly indicate the need for broader study of these networks under swelling and/or extension conditions and of similar networks with different crosslinking agents. 6 refs.

**082847 CONFORMATION AND DYNAMIC ASPECTS OF POLY( $\gamma$ -N-OCTADECYL L-GLUTAMATE) IN THE SOLID STATE AND LIQUID-CRYSTALLINE STATE AS STUDIED BY VARIABLE-TEMPERATURE  $^{13}\text{C}$  CP/MAS NMR SPECTROSCOPY.**  $^{13}\text{C}$  CP/MAS NMR experiments are carried out for poly( $\gamma$ -n-octadecyl L-glutamate) as a function of temperature, in order to elucidate dynamic and conformational features in the solid state and liquid-crystalline state. From these experimental results, it is found that the main chain of the polymer takes on a right-handed  $\alpha$ -helical conformation within the temperature range from 27 to 100°C, while long n-alkyl side chains take on an all-trans zigzag conformation in the crystalline state at room temperature and are in a mobile state above 35°C. Further, it is found that at about 40°C the  $\alpha$ -helical main chain in the liquid-crystalline phase is undergoing molecular motion at a frequency of ca. 60 kHz. (author (Author abstract) 25 refs.

**082848 RADICAL IONS OF POLYSILASTYRENE.** The absorption spectra of radical ions of polysilastyrene have been measured in rigid matrices at 77 K as well as in solution at room temperature by using  $\gamma$ -irradiation and pulse radiolysis methods. The radical anion with  $\lambda_{\text{max}}$  at 365 nm was observed in irradiated 2-methyltetrahydrofuran, while the radical cation with two absorption bands at 358 and 2000 nm was observed in irradiated n-butyl chloride at 77 K. Upon thermal annealing, the

infrared band showed a blue shift to 1700 nm, which is attributed to the geometrical reorientation of pendant phenyl groups from the unrelaxed to relaxed dimer radical cation conformation. (Edited author abstract) 14 refs.

**082849 FOURIER TRANSFORM INFRARED SPECTROSCOPY OF SOME MISCIBLE POLYBENZIMIDAZOLE/POLYIMIDE BLENDS.** The IR spectra of representative miscible aromatic polybenzimidazole/aromatic polyimide (PBI/PI) blends have been studied. Composition-dependent frequency shifts of up to 55  $\text{cm}^{-1}$  in the N-H stretching band of PBI and up to 6  $\text{cm}^{-1}$  in the carbonyl stretching bands of PI were observed. These shifts were removed by thermally induced phase separation. The results suggest that the miscibility of these blends derives from specific intermolecular interactions involving the >NH and carbonyl groups. (Author abstract) 15 refs.

**082850 CARBON-13 NUCLEAR MAGNETIC RESONANCE CHARACTERIZATION OF NETWORK SYSTEMS.** Solid-state C-13 NMR measurements are utilized to characterize the tetrafunctional epoxy, tetraglycidyl(diaminodiphenyl)methane, and the tetrafunctional amine, diaminodiphenyl sulfone. Intermolecular effective ether cross-links, amine junction points, and extent of reaction of the amine and epoxy are measured for the polymerization. Chemical reactions in the epoxy-amine system are discussed, and the reactivity ratio of the epoxy-amine system is calculated. Junction point measurements are made by the use of the dipolar dephasing relaxation experiment. The experimental data collected with C-13 NMR are then compared with the calculated data from a model developed in this laboratory. The information obtained in this study is sufficient to calculate the molecular weight between cross-links. (Author abstract) 33 refs.

**082853 INTERPRETATION OF THE FRAGMENTATION PATTERNS IN STATIC SIMS ANALYSIS OF POLYMERS. PART I. SIMPLE ALIPHATIC HYDROCARBONS.** A number of simple aliphatic hydrocarbon polymers have been studied by static SIMS. The low-mass positive spectra reflect structural differences in the polymeric structure, which result in characteristic fingerprint spectra. Unsaturation and differences in branching lead to very distinct spectral features which show promise for the application of SIMS as an analytical technique in polymer-related areas. An attempt is made to interpret the spectra in terms of molecular structure, fragmentation mechanisms and ion stabilities. The chemical nature of ion beam damage in PE and PP was studied to some extent. (Author abstract) 27 refs.

**082854 RAMAN SPECTRA OF POLYPYRROLE AND ITS 2,5- $^{13}\text{C}$ -SUBSTITUTED AND C-DEUTERATED ANALOGUES IN DOPED AND UNDOPED STATES.** Raman and optical absorption spectra were studied on electrochemically polymerized polypyrrole in as-polymerized doped (highly conductive), partially undoped and substantially undoped 'neutral' (insulating) states. Vibrational assignments were made on the basis of data of 2,5- $^{13}\text{C}$ -substituted and C-deuterated derivatives. The Raman result of the neutral polymer is consistent with the  $\alpha,\alpha'$ -linked all-s-trans coplanar and conjugated structure. In the as-polymerized polymer there exist both radical cation and dication in which the bond orders of  $\text{C}_3\text{C}_4$  and inter-ring CC are increased as compared to those in the neutral polymer. The structural distortion in the dication is greater than that in the radical cation. Changes in optical absorption and Raman spectra during reduction (undoping) were explained by the conversions of the dication to the radical cation and the radical cation to the neutral species. (Author abstract) 45 refs.

**082855 INTERFACIAL TENSION AND SURFACE HYDROPHILICITY IN SYSTEMS OF SOLID POLYMERS IN CONTACT WITH AQUEOUS SOLUTIONS.** The nondispersive part of the interfacial tension between polymer solids and aqueous solutions has been determined by contact angle measurements on photooxidized polystyrene (PS). It is shown from contact angle measurements in air and in octane that the expression for  $\gamma_{\text{saq}}$  includes a term that is proportional to  $\gamma_{\text{saq}}^n$  and not to  $\sqrt{\gamma_{\text{saq}}}$  as is often assumed. The proportionality factor is taken as an expression of the hydrophilicity of the surface. The development of oxidized surface groups was followed by ESCA. It is concluded that the degradation of PS upon UV curing includes an attack on the aromatic groups followed by a ring opening. The hydrophilicity shows a sharp increase at a certain oxidation level, which we interpreted to be due to the ring opening. (Author abstract) 30 refs.

**082856 RHEO-OPTICAL FOURIER-TRANSFORM INFRARED SPECTROSCOPY OF POLYMERS: 14. SEGMENTAL ORIENTATION AND STRAIN-INDUCED CRYSTALLIZATION OF A POLY(ETHER URETHANEUREA) ELASTOMER.** The versatility and potential of rheo-optical Fourier-Transform infrared (FTIR) spectroscopy is demonstrated with reference to the characterization of segmental orientation in a poly(ether urethaneurea) elastomer. The rheo-optical data show that the soft and hard segments of the polymer deform by different orientation mechanisms. Thus, the soft segments exhibit an almost perfect reversibility of orientation and disorientation in loading and unloading cycles, whereas the deformation of the hard

segments is dominated by a significant reorganization of their morphology. Furthermore, rheo-optical FTIR spectroscopy provided an extremely sensitive tool for detecting the onset, progress and decay of strain-induced crystallization of the soft segments during the mechanical treatment of the elastomer. (Author abstract) 30 refs.

**082858 <sup>13</sup>C-NMR STUDY ON THE CHAIN TERMINAL STRUCTURE OF POLY-1, 3-PENTADIENE POLYMERIZED WITH RARE EARTH CATALYST.** The sequence distribution and the terminal structures of poly-1, 3-pentadiene chains obtained by rare earth catalyst and the effect of polymerization temperature on the microstructure of the polymer have been investigated by the <sup>13</sup>C-NMR method. According to experimental results, it was supposed that the terminal active growing chain of the polymer would be four types of anti- and syn- $\eta^3$ -allyl structures. When polymerization temperature was reduced, the content of cis-1,4-poly-1,3-pentadiene increases. It can be explained by isomerization between anti- and syn- $\eta^3$ -allyl. The process forming the trans-1,2 unit instead of the 3,4-unit was also described. (Author abstract) 6 refs.

Xie, Demin (Acad Sinica, Changchun, China); Gong, Zhi; Wang, Fosong. *Chin J Polym Sci (Engl Ed)* v 5 n 2 1987 p 109-113.

**082859 STUDY ON SEQUENCE DISTRIBUTION OF 3,4-POLYISOPRENE BY <sup>13</sup>C-NMR.** Isoprene can be polymerized with an Fe(acac)<sub>3</sub>-phen-AlEt<sub>3</sub> catalyst system into a polymer mainly containing a 3,4-unit and capable of crystallizing to some extent. The <sup>13</sup>C-NMR spectra of 3, 4-polyisoprene synthesized with an Fe-catalyst system were investigated, and the sequence distribution of cis-1,4 and 3,4-units was discussed. Results showed that the contents of cis-1,4, trans-1,4 and 3,4-units calculated from different carbon types were satisfactorily identical, indicating correct assignments of these peaks. (Author abstract) 8 refs.

Xie, Demin (Acad Sinica, Changchun, China); Sun, Qing. *Chin J Polym Sci (Engl Ed)* v 5 n 2 1987 p 114-119.

**082860 HOLE-BURNING EXPERIMENTS IN DOPED POLYMERS UNDER UNIAXIAL AND HYDROSTATIC PRESSURE.** The hole-burning technique makes possible the study of extremely small strain-induced shifts and broadenings of quasi-homogeneous optical lines of dye molecules in polymer matrices. The polymers polyethylene, polymethylmethacrylate and polystyrene were doped with free base phthalocyanine and investigated under unidirectional and hydrostatic pressure. Since the pertinent equations for pressure-induced shifts can be linearized at the small pressures used (<0.1 MPa), one can calculate values for the hydrostatic compressibility  $\kappa$  if one assumes that a  $R^{-6}$ -law governs the molecular interactions responsible for the solvent shift. The optically determined compressibility values agree with the mechanically measured values within 10-20%. (Author abstract) 30 refs.

**082861 ELECTRON DELOCALIZATION IN POLY(ANILINE).** The appropriate quantum-mechanical description for electron-conducting polymers hinges upon whether behavior is better explained with delocalized wave functions, the band model approach, or by localized states confined to small segments of the polymer. Previous electron spin resonance studies of poly(aniline) have suggested that the energy band description is more appropriate. The authors examine theoretically and experimentally the ESR, voltammetric, and spectroscopic properties of poly(aniline) and its shortest oligomer, N,N'-diphenyl-p-phenylenediamine. Using an empirical Hamiltonian matched to the oligomer's hyperfine structure, the authors find it possible to describe the properties of both oligomer and polymer, supporting the validity of the delocalized representation. (Edited author abstract). 34 refs.

**082862 INFRARED STUDIES OF OPTICALLY EXCITED POLYDIACETYLENE.** Photo-induced absorption (PA) is observed for the polydiacetylene PDA-10H in the infrared which is found to be consistent with the photogeneration of charged bipolarons. No comparable PA is seen in PDA-TS, a result that is consistent with photo-excitation leading to the formation of triplet excitonic bipolarons. Persistent effects are observed for PA in PDA-10H indicating a long carrier lifetime due to trapping. Electron correlation is significant and shifts the electronic transitions to lower energy in PDA-10H so that overlap of electronic and vibrational transitions occurs. This overlap leads to strong anti-resonances in the PA due to electron-photon interaction. (Author abstract) 26 refs.

Pratt, F.L. (Univ of Oxford, Oxford, Engl); Wong, K.S.; Hayes, W.; Bloor, D. *J Phys D* v 20 n 11 Nov 14 1987, Pap Presented at the Polym Phys Group Meet on Electroact Polym, London, Engl, May 14 1987 p 1361-1366.

**082863 PHOTOLUMINESCENCE OF CONDUCTING POLYMER P3MT.** The photoluminescence spectra of conducting polymer P3MT with different doping densities and temperatures are reported and the photoluminescence mechanisms of P3MT are discussed. It is demonstrated experimentally that there are three kinds of radiative transitions, the direct interband transition, the recombination of exciton and radiative transition between bipolaron level and edge of band for the conducting polymer at excitation of 5145 Angstrom laser. The photoinduced bipolaron and the pinning effect of ionized dopant on bipolaron have been observed. 3 refs.

## Spectrum Analysis

**082864 PMR-, IR-, AND UV-SPECTROSCOPIC STUDIES OF PRODUCTS OF REACTION OF DICYANDIAMIDE WITH FORMALDEHYDE, METHYLOL AND METHYLENE ETHER DERIVATIVES.** Amido- and amino-formaldehyde resins comprise an important class of polymers. The least investigated are the dicyandiamide-formaldehyde resins (DFR), whose use is promising for the preparation of hydrophobic, fireproof and other polymers. From the study of the spectra of DFR, certain conclusions can be made on their composition. Facts show that the polymerization of DFR proceeds mainly with the formation of methylene-ether bridges, and the methyl groups remain as the terminal groups. This is indicated by the high content of oxygen in the polymer - 26.6% (determined in a CHN-3 analyzer). 10 refs.

**082865 CALCULATION OF FREQUENCIES AND INTENSITIES IN THE IR ABSORPTION SPECTRUM OF POLY(TETRAFLUOROETHYLENE).** Among the vibrational spectra of polymers, the spectrum of poly(tetrafluoroethylene) (PTFE) is of special interest for theoretical analysis. Observed vibrational spectra of PTFE have a number of characteristics not yet satisfactorily explained. Together with the doubling of the IR bands at 640-625  $\text{cm}^{-1}$  and the Raman lines at 595-575  $\text{cm}^{-1}$  repeatedly discussed in the literature, we note the large half-width and complex shape of the absorption bands near 1210 (half-width about 52  $\text{cm}^{-1}$ ) and 520  $\text{cm}^{-1}$  (half-width of 25-35  $\text{cm}^{-1}$ ) and also the relation of the shape of these bands to the method of sample preparation. It is possible to enumerate a series of possible reasons for the appearance of wide bands in the polymer spectrum. For quantitative evaluation of the effect of the enumerated factors on the polymer spectrum. The frequencies and intensities in the vibrational spectra of the PTFE models were calculated. 14 refs.

**082866 MOLECULAR MOTIONS IN POLY(ETHYLENE OXIDE) SOLUTIONS.** The motions of solvent and solute molecules in solutions of poly(ethylene oxide) have been investigated by neutron inelastic scattering measurements. Both the concentration dependence and the influence of the molecular weight of the PEO molecules were studied. It is shown that there exists a strong concentration dependent interaction between a PEO molecule and the surrounding water which affects both the translational and the rotational motions of the water molecules. Thus there is a clear indication of the presence of a hydration shell around each PEO molecule within which the motions of the water molecules are strongly hindered. In carbon tetrachloride solutions the results indicate that there exists a weak interaction of hydrodynamic origin between solvent and solute molecules. (Author abstract) 37 refs.

**082868 OPTICAL ABSORPTION OF METAL-LOADED POLYMER FILMS PREPARED BY VACUUM EVAPORATION.** We have previously reported some properties of complex thin films prepared by co-evaporating polypropylene (PP) and metals so as to include of the order of 0.1 wt% of copper or gold. The gold-loaded films are less contaminated than copper. In the present work we have studied the optical absorption edges of thin PP films and films containing gold to see whether some estimate of the nature of the energy bands in vicinity of the absorption edge could be made. 9 refs.

**Stability** See Also MONOMERS—Polymerization; MONOMERS—Synthesis; POLYAMIDES—Synthesis; POLYVINYL CHLORIDE—Curing.

**082869 COMPUTER-AIDED MOLECULAR MODELING OF POLYMERS. III. ENTHALPY OF POLYMERIZATION AS A MEASURE OF STABILITY.** A formalism of computational chemistry methods is presented to estimate the stability of vinyl polymers. This approach takes into account changes in electronic energy upon polymerization using quantum mechanical methods and contributions of the conformational energetics of the polymerized state using a molecular mechanics force field. A work term, PAV, based upon the molecular volume difference between the monomer and the reactant, is shown to be negligible. (Edited author abstract) 14 refs.

**082870 APPLICATION OF CONTINUOUS THERMODYNAMICS TO THE STABILITY OF POLYMER SYSTEMS. II.** A determinant criterion for the critical state in solutions and mixtures of polydisperse polymers is established within the general framework of Gibbs theory. The treatment continues an earlier paper by considering more general Gibbs free energy relations: The function replacing the  $\chi$ -term in the classic Flory-Huggins equation is permitted to depend on a finite number of moments of the polymer distribution(s) so as to embrace most Gibbs free energy relations of practical use. The new criterion leads to a very large reduction of computer time and of needed storage capacity compared to the traditional Gibbs determinant criterion. (Edited author abstract) 14 refs.

**082871 THERMAL STABILITY AND KINETICS OF DECOMPOSITION OF POLYPHENYLSILSES-QUIOXANES AND SOME RELATED POLYMERS.** The thermal stability and the mechanism and kinetics of decomposition of the ladderlike polymer polyphenylsilses-quioxane (PPS) and some related polyorganosiloxanes were studied by means of thermal analysis, pyrolysis GC, GC-MS, and other methods. The experimental results show that ladderlike PPS is thermally more stable than the analogous single chain polymer PDPS. Above 505°C, PPS decomposes by mechanisms of phenyl group elimination and carbonization. The apparent activation energy of the decomposition of PPS is about 270 kJ/mol, which is much higher than those of other polyorganosiloxanes studied. Copolymers of PPS with PDPS and PDMS have intermediate thermal properties. MW and MWD have a negligible effect on the stability of PPS while chlorination lowers the heat-resistant properties significantly. (Author abstract) 11 refs.

**082872 ESTIMATE OF THE STABILIZATION ENERGY OF CATION RADICALS FORMED IN POLY(N-VINYLCARBAZOLE) AND ITS DIMER MODEL COMPOUNDS BY AN ION RADICAL TRANSFER METHOD.** The stabilization energies of the carbazole cation radicals were estimated by the ion radical transfer method. The carbazole cation radicals ( $Cz^+$ ) were formed photochemically in poly(N-vinylcarbazole) (PVCz) and its dimer model compounds, and they were stabilized by the interaction with neighboring carbazole ( $Cz$ ) chromophores. Due to the stabilization, the  $Cz$  cation radical in PVCz is not transferred to a cation radical acceptor, 4-(dimethylamino)styrene (DMASt), which has a lower oxidation potential than the  $Cz$  chromophore, whereas the cation radical of monomeric N-ethylcarbazole is transferred to DMASt easily. The stabilization energies of  $Cz^+$  were evaluated from the rate constants of cation radical transfer to DMASt. (Edited author abstract) 42 refs.

**082876 DETERMINATION OF SMALL AMOUNTS OF ORGANIC HYDROPEROXIDES IN THE PRESENCE OF HINDERED AMINE LIGHT STABILIZERS AND THEIR NITROXYLS.** A method for the quantitative determination of hydroperoxide (ROOH) in the presence of hindered amine light stabilizers (HALS) and/or their nitroxyl free radical derivatives has been elaborated. The method is based on the quantitative reduction of hydroperoxides by triphenyl phosphine. The resulting compounds (alcohols) are then determined by GLC using the internal standard technique. The method has been tested on the hydroperoxides derived from 2,4-dimethylpentane. Its sensitivity and reproducibility appear to be comparable with other methods for ROOH determination but, unlike the latter, it has the advantage that its results are not influenced by the presence of HALS and/or their nitroxyl radical derivatives in the analyzed medium. **082878 PHOTOSTABILIZING EFFECT OF 5-HYDROXY-3-PHENYL-AMINO-1-PHENYL-3,5-DIHYDROBENZENE DERIVATIVES IN POLYCHLOROPRENE.** The photostabilization of polychloroprene in the presence of four derivatives of 5-hydroxy-3-phenylamino-1-phenyl-3,5-dihydrobenzene was studied. The inhibitory activity of the added compounds is proportional to their extinction coefficient values. The addition of singlet oxygen quenchers such as  $\beta$ -carotene reduces the rate of degradation of polymer solutions. This means that singlet oxygen may involve the photooxidation process. The influence of the most effective stabilizer was also examined using Differential Scanning Calorimeter (DSC) technique; the obtained results indicate the photostabilizing effect of it. (Author abstract). 6 refs.

**082880 CRITICAL STRAIN TO DEAD BEND.** This letter is an attempt to show the relationship between fibrillar morphology, compressive weakness, shear banding, inelastic deformation, and dead bending. In doing so a model for estimating fibril lengths is presented. The model provides a reasonable and semi-quantitative description of the requirements for dead bending - well-defined fibrils with diameters up to a few hundred micrometers and little lateral interaction. The model also suggests the relationship of shear banding to the onset of compressive inelastic deformation in fibrillar polymers. 8 refs.

**082881 ANALYSIS OF PLANE-STRAIN NECK PROPAGATION IN VISCOPLASTIC POLYMERIC FILMS.** The influence of material strain-rate sensitivity on neck propagation during the cold drawing of polymeric films is examined. The entire load-deformation behavior of a rectangular specimen as well as the evolution of the specimen profile and the stress and strain distributions at various stages of the deformation process are computed. The numerical analysis is based on the implementation of a finite-element scheme via the virtual work principle for elastic-viscoplastic material behavior. Parametric studies are also performed to investigate the effects of various variables on necking and neck propagation. Comparisons with rate-independent material response are also presented. (Author abstract) 7 refs.

**082883 TORSIONAL POTENTIAL AND STRAIN ENERGY DISTRIBUTION IN AN EXTENDED CHAIN UNDER STRESS.** Torsional potential  $V(\phi)$  for the single bond transformation in an extended hexadecane, subjected to elongation, has been determined by molecular mechanics calculations. The stored elastic energy significantly modifies the potential  $V(\phi)$ , the conformational energies and the barriers of transition. Apart from the 'soft' torsional coordinate, elastic energy is also dissipated considerably by bond stretching and angle bending. Maximal variations of the valence coordinates occur in the vicinity of the torsional defect and dampen along the chain. At higher elongation, the gauche minimum on the potential  $V(\phi)$  disappears and the calculations predict the abrupt gauche to trans transition. The energetics of torsion of a deformed chain are compared with the experimental data on the hydrodynamic extension of polymers in dilute solution by elongational flow. The calculations also provide details of a single bond transformation mechanism at conformational interconversions in a long chain, proposed by E.Helfand. (Author abstract) 15 refs.

**Stresses** See Also PLASTICS FILMS—Structure; POLYSTYRENES—Solutions.

**082884 THERMAL STRESS IN POLYMER SPHERULITES.** The aim of this letter is to show that the curvilinear anisotropy of the spherulite causes a peculiar thermal stress distribution. To make the problem tractable it is assumed that in cases where the spherulites are equiaxed, the actual deformation due to thermal strain can be deduced by analyzing the deformation within a prototype spherical 'test' spherulite. The 'test' spherulite is embedded in an isotropic matrix to which is assigned the bulk polymer properties. Within an unconstrained spherically anisotropic solid, thermal stresses will arise. These thermal stresses may be partially responsible for fatigue cracking which has been observed in pipelines made of semi-crystalline polymers. These materials are susceptible to corrosion cracking which may be accelerated by hydrostatic tensile stresses. 7 refs.

**082885 STUDIES ON BIREFRINGENCE AS A FUNCTION OF STRAIN IN CROSSLINKED POLYMERS UNDER CREEP CONDITIONS.** It is shown that the interconnection between the strain and birefringence for certain crosslinked polymers under creep conditions is described by a linear equation. In the case of the polymers studied, the change in optical sensitivity to the stress differs as between the time and temperature. The authors consider the results in connection with the isochronic thermo-optical curves for the total  $C_{\sigma}$  constructed by treatment of a family of creep curves in the region of times of existence of a provisionally equilibrium state and additional branch 3' reflecting the change in the total  $C_{\sigma}$  in the specimen during cooling. Apart from generally known information which follows from these curves they are also useful for plotting the elastic character of the stress  $C_{\sigma}$  against the temperature. (Edited author abstract) 12 refs.

**082886 STRESS RELAXATION AND CHEMICAL KINETICS IN PAIRWISE ASSOCIATING POLYMERS.** Within the framework of the tube model, a theoretical study is made of the dynamics of a concentrated system of long flexible macromolecules, each of which has a single functional end group that can associate with another such group to make a dimer. When the dissociation time of the dimer ( $T_{\text{break}}$ ) is very large compared with  $T_d$ , the disengagement time of an undimerized chain (or 'monomer'), the zero-shear viscosity of the system approaches  $\eta = (16q + 1)\eta_0/(2q + 1)$ , with  $\eta_0$  the viscosity of pure monomers and  $q$  the equilibrium ratio of dimers to monomers. (Edited author abstract) 16 refs.

Cates, M.E. (Univ of California, Santa Barbara, CA, USA). *Macromolecules* v 21 n 1 Jan 1988 p 256-259.

**082887 EFFECT OF STRESSES ON POLYMER OXIDATION. QUANTITATIVE ASPECTS. II. PLASTICS.** The authors examine semicrystalline polymers in a highly elastic state, viz., high-density polyethylene (HDPE), low-density polyethylene (LDPE), isotactic polypropylene (PP), polyamides of different chemical structure, PE/PP mixtures, and a few others. Besides, data for polymers in the glassy state will also be presented, although they are of lesser interest in regard of the effect of structural strains on reactivity because of the long relaxation times involved. Also analyzed is the effect of stresses on the structural parameters and properties of polymer. To take into account these data, it is possible to describe quantitatively the peculiarities of the chemical reaction kinetics in stressed polymers. Experimental results show that the nature of structural stresses are the same in both small and large molecules. Therefore, the regularities obtained for the model objects should be valid for more complicated polymer systems. Naturally, appropriate corrections must be made to take into account the specific state of the polymers. 96 refs.

Popov, A.A. (USSR Acad of Sciences, Moscow, USSR); Zaikov, G.E. *J Macromol Sci Rev Macromol Chem Phys* v C27 n 3-4 1987-1988 p 343-377.

**082888 EFFECT OF STRESSES ON POLYMER OXIDATION. QUANTITATIVE ASPECTS. III. KINETICS.** The main purpose of this review is consideration of the chemical reaction kinetics in stressed polymers on the quantitative level and description of the reasons for and mechanism of stress effect on kinetics. Therefore we compare the stress effect on the reaction kinetics of model and polymer compounds and take into account variations of structural, physical, and dynamic parameters in stressed polymers. It is shown that the stresses applied during the experiment may considerably affect the initial morphology of the polymer specimen. The primary effect is irreversible deformation involving either a complete change of the initial submolecular structure (from spherulitic to fibrillar) or some alteration of the existing structure (post-orientation). One consequence is the variation of the permeability and mobility parameters. 139 refs.

**082889 COMPUTER SIMULATION OF POLYMERIC MATERIALS. I. STRESS-STRAIN BEHAVIOR.** A model of polymeric materials has been developed that includes many of the features of condensed-phase polymer chain dynamics, central among them chain relaxation via conformational motion. The model consists of a number of chains of particles that are connected by bonds with multiwelled potentials to approximate the energetics of conformational motion. Interactions between particles on adjacent chains are modeled by short range repulsive potentials. We have examined the stress-strain behavior of the model using molecular dynamics simulations and find qualitative agreement with the observed experimental behavior of polymeric materials. (Author abstract) 6 refs.

**082890 ENERGY STORAGE IN POLYMER CHAINS UNDER STRESS.** The local conformation and storage of energy in individual polymer chains during a deformation of a bulk polymer sample are examined by the computer simulation of a relatively simple model. It is shown that as the interaction between the chain atoms and surrounding medium increases, rotational angle motion is suppressed during the deformation, and large amounts of energy are stored in backbone bond angle and bond length distortions. The relationship of this phenomenon to  $T_g$  and the implications for chain relaxation are discussed. (Author abstract) 17 refs.

Cook, Robert (Lawrence Livermore Natl Lab, Livermore, CA, USA). *J Polym Sci Part B* v 26 n 7 Jul 1988 p 1349-1359.

**082891 FORM OF THE LINE OF PROTON MAGNETIC RESONANCE AND THE IRREGULARITY OF THE NETWORK STRUCTURE OF CROSSLINKED POLYDIMETHYLSILOXANES.** An analysis is made of the form of the PMR signal of weakly crosslinked polydimethylsiloxanes swelling in a solvent. The line of complex form observed may be represented by the superposing of two signals. One belongs to the chains of the network the degree of crosslinking of which determined by the PMR method corresponds to the degree of crosslinking determined from the equilibrium swelling of the sample. The narrower component apparently corresponds to a sparse network with a mean distance between nodes greater by at least one order than for the first. The free ends of the macromolecules must contribute to the second signal. With the approach it is possible to evaluate the fraction of macromolecules responsible for the two signals. (Author abstract) 8 refs.

**082892 STRUCTURE AND SPECIAL FEATURES OF THE SWELLING AND TITRATION OF POLYCOMPLEXES - PRODUCTS OF THE MATRIX POLYCONDENSATION OF UREA AND FORMALDEHYDE ON POLYACRYLIC ACID.** The structure of urea-formaldehyde polymer formed as a result of the matrix polycondensation of urea and formaldehyde in the presence of polyacrylic acid depends on the pH. At pH > 3.8, its chains contain mainly N,N'-substituted fragments or urea (as when there is no matrix), and at pH < 3.8, an appreciable amount of N,N'-substituted fragments. The effect of the stability of the complex formed between the growing chain and the matrix on the structure of the daughter chain formed as a result of the matrix polyreaction is discussed. The kinetics of the swelling and titration of polycomplexes of polyacrylic acid with urea-formaldehyde are studied, and it is shown that

there are essential differences in the behavior of polycomplexes obtained at pH values above and below 3.8. (Author abstract) 9 refs.

#### 082893 TRY LIQUID CRYSTAL POLYMERS.

Physical properties and applications are presented for liquid crystal polymers, or LCPs, which are made of rigid, rod-like ordered molecules that maintain a crystalline order even on melting. They can be classified by the type of molecular orientation that they display, either nematic (crystals are all aligned in the same direction but in random order) or smectic (crystals are all aligned in the same direction and are in distinct layers). LCPs have dimensional stability that is superior to other high-performance engineering plastics, thermoset epoxy, and ceramics. The tensile strength of LCP compounds actually increases at reduced thicknesses because of orientation effects. It is shown that their features make metal and thermoset replacement and displacement of traditional engineering resins both feasible and cost-effective.

Dole, John R. *CHEMTECH* v 17 n 4 Apr 1987 p 242-245.

#### 082894 FORMATION OF SUPRAMOLECULAR STRUCTURES IN AMORPHOUS POLYMERS.

A scheme of the formation of the elements of the supramolecular structure of polymers on the basis of the Lifshits theory of the 'coil-globule' transition is proposed and analyzed. The scheme helps to explain a number of phenomena observed experimentally during the formation of polymer bodies from solutions (the influence of the quality of the solvent on the properties, plasticization and antiplasticization, etc.) and to predict ways of obtaining polymer bodies with the desired structure and properties. (Author abstract) 12 refs.

#### 082895 COMPARATIVE STUDY OF PROPERTIES OF POLY(IMIDOPHENYLQUINOXALINES) AND POLY(AMIDOPHENYLQUINOXALINES).

Mechanical and thermal properties have been compared for two pairs of isomeric poly-(imidophenylquinoxalines) and poly(amidophenylquinoxalines), the polymers of each pair differing in the localization of phenyl substituents in the side groups. The chemical structure affects the deformation and ultimate characteristics owing to the fact that specific interaction between the phenylquinoxaline groups are realized between adjacent macromolecules in one polymer but inside the repeat unit in the second polymer; as a result, the deformation parameters are worsened and the glass-transition temperature is lowered in the second instance. (Author abstract) 5 refs.

#### 082896 EFFECT OF CHEMICAL STRUCTURE AND CRYSTALLINITY ON SORPTION, DIFFUSION AND CHEMICAL STABILITY OF POLYURETHANEACETALS.

The diffusion of water in non-isocyanate polyurethaneacetals (PUA) of various kinds and compositions has been studied. The direct relationship between the composition of polymers, their degree of crystallinity, morphology and diffusional characteristics has been demonstrated. It has been shown that by changing the polymer composition one can obtain hydrated polymer systems of every type, hydrophobic, hydrophilic and moderately hydrophilic. The kinetics of hydrolytic degradation of PUA in HCl solutions (pH=0.1) between 20 and 75°C has been investigated. Hydrolysis of acetal bonds has been found to occur in the amorphous phase of a polymer sample, which is mostly formed by the fragments of urethane glycol. The influence of morphology on PUA diffusional characteristics and

their stability to hydrolysis has been determined. It has been shown that the physico-chemical properties of PUA can be regulated without the introduction of new compounds. (Author abstract) 19 refs.

#### 082897 POLYMER COMPLEXES STABILIZED THROUGH HYDROGEN BONDS. INFLUENCE OF 'STRUCTURE DEFECTS' ON COMPLEX FORMATION: VISCOMETRY AND FLUORESCENCE POLARIZATION MEASUREMENTS.

The structure of polymer complexes stabilized through hydrogen bonds can be much influenced by the presence of nonactive groups (structure defects) on the polymer chains. In this paper, two very simple homopolymer/copolymer systems are studied: the homopolymer is a polybase, polyoxyethylene (PEO) or polyvinylpyrrolidone (PVP), and the copolymer a partially neutralized poly(acrylic acid) (PAA). The acrylate groups on PAA chain behave as structure defects. Viscometry provides information about macroscopic structure of polymer complex in solution while fluorescence polarization is especially adapted for the study of the local mobility of polymer chains. Two kinds of structure are found: the first one is compact and implies a low viscosity of the mixture, eventually precipitation occurs. The second one is a highly branched structure, close to a gel, which leads to a very high increase in viscosity. (Edited author abstract) 21 refs.

#### 082898 NETWORK CHARACTERIZATION OF A POLYFUNCTIONAL CROSSLINKED SYSTEM.

In this paper a method proposed recently by D.R. Miller and C.W. Macosko is used for calculation of the network structure of a polyfunctional amine polymerizing with a bifunctional epoxy resin. Finite chain probabilities are derived for amine functionalities, taking the values of 5 and 6. The values of  $v_c$  derived by this method are tested with those obtained from the equation for rubber elasticity. Some further assumptions for networks with short chains are made for both this method and the classical theory of rubber elasticity. A satisfactory approximation between theoretical and experimental values of  $v_c$  is then obtained. (Edited author abstract) 16 refs.

#### 082899 STRUCTURE OF ONE CRYSTAL MODIFICATION OF POLY(3,3-DIETHYL OXETANE).

The determination of the crystalline structure of one of the two forms of poly(3,3-diethyl oxetane) detected by calorimetric and X-ray analysis is described. The unit cell is monoclinic with parameters:  $a=1.333(7)$  nm,  $b=0.577(2)$  nm,  $c$  (fiber axis)= $0.474(2)$  nm and  $\gamma=91.1(5)^\circ$ . After computerized refinement, the final model has a crystallographic R-value of 0.18. The molecular conformation is a planar zigzag, and two chain segments pass through the unit cell. The chain conformation and the packing of chains are discussed in detail and compared with other polyoxetanes. (Author abstract) 9 refs.

#### 082900 STRUCTURE OF POLY(P-PHENYLENE SULPHIDE).

We have examined the unit-cell structure of the import high-strength polymer, poly(p-phenylene sulfide) (PPS); this has recently been in dispute, with two different models proposed from oriented and unoriented polycrystalline specimens, respectively. Having obtained single crystals of PPS from solution and from thin films of the melt (the latter in both flat-on and edge-on orientations), we determined the lattice dimensions of the orthorhombic unit cell using electron diffraction. These

are  $a=8.68$  Å,  $b=5.66$  Å and  $c=10.26$  Å, in agreement with the original model based upon alternating  $\pm 45^\circ$  inclinations of the phenyl rings to the plane of the sulfur bonds. (Edited author abstract) 15 refs.

#### 082901 MECHANICAL AND DIELECTRIC RELAXATIONS OF POLY(HYDROXY ETHERS): 1. LOW-TEMPERATURE RELAXATIONS.

Mechanisms for the low-temperature relaxations were investigated for poly(hydroxy ethers) prepared by the polyaddition reaction of diglycidyl ethers with diphenols. Two relaxations, denoted  $\beta$  and  $\beta'$ , are observed at  $-70$  and  $+40^\circ\text{C}$  (for a frequency of approx. 1 Hz), respectively. It is revealed by comparing the mechanical relaxation with the dielectric relaxation that the  $\beta$  relaxation is a complex relaxation, that is, the overlap of the relaxation of hydroxy ether segment with that of other parts in the polymer chain, and that the  $\beta'$  relaxation is due to the motion of the phenylene group in the polymer chain. In the acetylated poly(hydroxy ethers), the relaxation of the hydroxy ether segment disappears and a new relaxation due to the motion of the acetylated segment appears near  $0^\circ\text{C}$ . This new relaxation is superimposed upon the  $\beta'$  relaxation. (Author abstract) 30 refs.

#### 082902 CHANGES IN THE SEGMENTED POLYETHERAMIDOURETHANE STRUCTURE UNDER THE ACTION OF POLAR LOW-MOLECULAR WEIGHT LIQUIDS.

The paper gives the results of a study of changes occurring in the domain structure of segmented polyetheramidourethane under the action of low-molecular weight liquids (alcohols, ketones) that are subsequently evaporated. Orientational characteristics of the treated films were determined from the dichroism of characteristic bands in the IR spectra ( $\nu_{C=O}$  for self-associated amide groups and  $\nu_{CH_2}$ ). It was found that such treatment results in the orientation of rigid segments changing from positive (horizontal to the stretching direction) to negative (perpendicular to the stretching direction). (Edited author abstract) 12 refs.

#### 082903 CONFORMATION AND OPTICAL ANISOTROPY OF SHORT CHAIN MOLECULES WITH MESOGENIC SIDE GROUPS.

Translational diffusion, sedimentation, characteristic viscosities and flow birefringence of samples and fractions of new comb-like polymers - series of alkoxyphenylacryloylox-ybenzoates - have been investigated. Relations have been obtained linking the molecular mass with viscosity, diffusion and sedimentation for polymethyl-phenyl-n-acryloylbenzoate. The Kuhn segments and the hydrodynamic diameter of the molecules have been determined. The value of the optical anisotropy of the segment of the macromolecules studied depends on the length of the chain side group and reflects the high intramolecular orientation order determined by the interaction of the mesogenic side groups. 12 refs.

#### 082904 $T_{1\rho}$ FROM THE TEMPERATURE DEPENDENCE OF CARBON-13 NMR CORRELATION TIMES $\tau_c$ .

We demonstrate that carbon-13 NMR average correlation times reach a visibly apparent asymptotic limit,  $(T/T_g)_{as}$  for 9 amorphous polymers and 4 semicrystalline polymers. The average value of  $T_c/T_g$  is 1.21, where  $T_c$  is the carbon-13 NMR collapse tempera-

ture. A linear correlation of  $T_c$  or  $T_{as}$  against  $T_g$  is demonstrated. This correlation can be used to define  $T_g$  in crystalline polymers if their  $T_c$  is known. (Edited author abstract) 26 refs.

**082905 STRUCTURE OF THE ENZYME-RESISTANT FRACTION OF TUSSAH SILK (ANTHRAEA PERNYI) FIBROIN.** This paper deals with the structural characteristics of the chymotrypsin-resistant and phosphatase-resistant fractions obtained by the action of these enzymes on tussah fibroin in solution. The relationship between the amount of the enzyme-resistant fraction and its chemical stability is also discussed. The results indicate that the enzyme-resistant fractions consist mainly of  $\alpha$  helix and  $\beta$  structures arising directly from the corresponding conformation of original tussah fibroin and that the  $\alpha$  helix is characterized by high chemical and thermal stability, regardless of the conditions of preparation and treatment, including enzyme treatment, thermal treatment, and immersion in methanol. 11 refs.

**082906 SOME APPLICATIONS OF GRAPH THEORY TO THE STUDY OF POLYMER CONFIGURATION.** The spatial configuration of polymer molecules in an Euclidean space depends on the adjacency of their units. The configuration dependent properties of the so called Gaussian polymer molecules of different structures can be expressed in terms of graph-theoretical categories such as the number of spanning trees, path lengths, generalized inverses and spectra of the Kirchhoff matrices of their graphs. We review here the methods and results concerning the distribution function of the square radius of gyration and its first moment, the mean square radius of gyration, for various types of polymer molecules. (Author abstract) 27 refs.

**082907 NEW POLYCARBOSILANE MODELS. 1. POLY(METHYLCHLOROSILYLENE)METHYLENE, A NOVEL, FUNCTIONAL POLYCARBOSILANE.** The aluminum trichloride catalyzed interchange of methyl and chlorine on silicon has been applied for the first time to the polycarbosilane series. Thus, poly[(dimethylsilylene)methylene] has been converted into a poly[(methylsilylene)methylene] the first functional polycarbosilane possessing an unambiguous linear skeleton. The considerable lowering of the average molecular weight, a consequence of the backbone cleavage, was accompanied by the formation of dimethylchlorosilyl groups as the chain terminals. These were characterized by  $^1H$ ,  $^{13}C$ , and  $^{29}Si$  NMR. (Edited author abstract) 8 refs.

**082908 HOMOPOLYGLACTURONAN NITROXYL AMIDES: HYDRATION-INDUCED MOTION.** In order to understand the relationship between the degree of polymer hydration, axis of rotation, and rotational frequency as well as rotational anisotropy, we measured the EPR spectra of variably hydrated nitroxyl amide spin-labeled plant homopolylacturonan (PGA) solids from 77 to 342 K. Detailed spectroscopic simulations using stochastic Liouville theory gave the best fit for experimental spectra assuming a moderate jump model with a rotational anisotropy of 3. The axis of rotation was the magnetic y axis of the nitroxyl amide which corresponds to rotational motion about the polymer's main chain. (Edited author abstract) 47 refs.

**082909 PREDICTION OF POLYMER CRYSTAL STRUCTURES AND PROPERTIES. A METHOD UTILIZING SIMULTANEOUS INTER- AND INTRAMOLECULAR ENERGY MINIMIZATION.** A method is described for using molecular mechanics to calculate in a unified manner, from transferable conformational energy functions, the packing parameters and energy, vibrational dispersion curves, heat capacity and thermodynamic functions, elastic constants, and refractive indices of polymer crystals. The inter- and intramolecular conformational energies are simultaneously minimized. This allows assessment of the effect of packing forces on the polymer helix parameters and the intramolecular geometry. In addition, the converged Newton-Raphson coefficient matrix used in minimization allows convenient vibrational analysis and calculation of the elastic constants of the crystal. (Author abstract) 18 refs.

**082912 RELAXATIONAL PROPERTIES AND STRUCTURE OF COMPOSITIONS BASED ON AN EPOXY RESIN MODIFIED WITH MONOEPoxide ESTERS OF FATTY ACIDS.** A relationship has been found between the position of dielectric loss peaks and the structure of epoxy polymers modified with monoepoxide esters, i.e., with products of epoxy oligomer esterification with fatty acids. It is shown that phase separation accounts for a second peak appearing in epoxy-epoxide ester polymers in the region for a relaxation. Parameters of dipole-segmental processes have been determined for structural elements of the studied systems. It was found that a lengthening of the fatty acid radical in the additive molecule leads to increased segmental mobility and to a fall in the glass-transition temperature. (Author abstract) 9 refs.

**082913 POSITRON ANNIHILATION METHOD OF STUDYING THE MICROSTRUCTURE OF POLYMERS IN RELATION TO THEIR DIFFUSIONAL PROPERTIES.** A wide selection of amorphous polymers in the high elastic and glass-like state is studied by a positron annihilation method. The parameters of the positron and positronium lifetime spectra are compared with the coefficients of diffusion of gases ( $H_2$ ,  $CH_4$ ) in the polymers and also with the glass transition temperatures

of the polymers. A correlation is established between the glass transition temperature and the free volume in the unordered regions of the polymer calculated on the basis of positron data. The coefficients of diffusion of gases in the rubbers are determined by the free volume in the unordered regions. (Author abstract) 24 refs.

**082914 STUDY OF THE STRUCTURE OF CROSS-LINKED POLYMERS - ADDITIVE BATCHES - BY MERCURY POROSIMETRY.** Diffusion of additives from cartridges prepared from oligoether acrylates, divinylbenzene and styrene, and a concentrate of commercial additives was studied and characterized by mercury porosimetry of the structure of the cross-linked polymer matrix. It was shown that the rate of discharge of the additives from the cartridge can be regulated by using monomers which produce a cross-linked matrix with a different pore size for synthesis. It follows from the analysis of the data obtained that the rate of discharge of additives can be regulated by synthesizing cartridges of different structure. To obtain macroporous samples with a high diffusion rate, it is necessary to use divinylbenzene or a mixture of divinylbenzene and styrene for synthesis. Addition of butyl methacrylate to divinylbenzene (1:1) decreases the rate of discharge of the additives by approximately 2 times. 6 refs.

**082915 CRYSTAL STRUCTURE OF ISOTACTIC TRANS-1,4-POLY(1,3-PENTADIENE). AN ANALYSIS BY CONFORMATIONAL AND PACKING ENERGY CALCULATIONS.** Conformational and packing energy calculations have been performed on isotactic trans-1,4-poly(1,3-pentadiene). Two different minimum energy conformations in agreement with the experimental chain axis have been found. One of them corresponds to a chain having the side methyl groups in a skew arrangement and the other to a chain having the side methyl groups in a cis arrangement with respect to adjacent double bonds. The two chains have been independently packed in the space group  $P2_12_12_1$  and two corresponding packing energy minima have been found. The calculations show that the skew arrangement, corresponding to the lowest conformational and packing energies, is preferred as opposed to the cis arrangement, even if the latter should be partially present in the crystal structure of oriented samples of the polymer. (Author abstract) 20 refs.

**082916 STRUCTURE OF POLY(D-(-)- $\beta$ -HYDROXYBUTYRATE). A REFINEMENT BASED ON THE RIETVELD METHOD.** The crystal structure of optically active microbial poly(D-(-)- $\beta$ -hydroxybutyrate) has been refined with the Rietveld whole-fitting method applied to powder X-ray diffraction data. This naturally occurring polymer gives rise to a very crystalline phase and therefore to very detailed and resolved powder profiles. Reliability of the refinement is discussed in relation to results obtained from previous studies on oriented-fiber diffraction patterns. The conclusion is that well-detailed powder profile data are highly discriminatory toward structural models not very dissimilar from each other. This result is considered an encouraging step toward a more general assessment of the accuracy of structural parameters obtained from best fitting of powder X-ray diffraction profiles. (Author abstract) 18 refs.

Brueckner, S. (Politecnico, Milan, Italy); Meille, S.V.; Malpezzi, L.; Cesaro, A.; Navarini, L.; Tombolini, R. *Macromolecules* v 21 n 4 Apr 1988 p 967-972.

**082917 VIBRATIONAL SPECTRA AND STRUCTURE OF POLYANILINE.** In this paper Raman and infrared spectra of polyaniline 1A, acid-treated 1A (1S), oxygen-treated 1A (1A(O<sub>2</sub>)), and doped 1A are studied. Assignments of vibrational spectra are made referring to the data of <sup>15</sup>N-substituted and C-deuterated polyanilines, N,N'-diphenyl-1,4-benzenediamine, and its derivatives. Key bands that are useful in determining the structures of various forms are elucidated and the relation between vibrational spectra, structures, and electrical properties is discussed. It is found that semiquinone radical cations of IP units exist only in the conducting forms of polyaniline, 2S and doped 1A, indicating that semiquinone radical cations play an important role in electrical conduction in polyaniline. (Edited author abstract) 36 refs.

**082918 LATTICE MODELS FOR BULK POLYMERS AT INTERFACES.** Lattice models for the prediction of conformational characteristics and thermodynamic properties at bulk polymer/solid and bulk polymer/gas interfaces are critically examined. Existing models are shown to fall into two broad categories: bond models, in which the probability of a chain conformation is expressed as a product of bond transition probabilities, and site models, in which the probability of a conformation is proportional to a product of probabilities characteristic of the sites occupied by successive chain segments. A general mathematical formulation is developed for bond models, which includes K.A. Dill and P.J. Flory's model of liquid bilayer membranes and E. Helfand's model of a pure homopolymer at an interface as special cases. (Edited author abstract) 11 refs.

Theodorou, Doros N. (Univ of California, Berkeley, CA, USA). *Macromolecules* v 21 n 5 May 1988 p 1391-1400.

**082919 STRUCTURE AND THERMODYNAMICS OF BULK HOMOPOLYMER/SOLID INTERFACES: A SITE LATTICE MODEL APPROACH.** A site lattice model for pure homopolymers at interfaces is derived, based on J.M. Scheutjens and G.J. Fleer's formulation for polymer solutions. Techniques are developed for the exploration of bond orientational characteristics at the interface. The model is implemented for monodisperse homopolymer systems of various molecular weights. Surface free energy is found to increase with chain length, as a result of entropic constraints at the interface. Bond orientation deviates from isotropy only within a narrow interfacial region, approximately six lattice layers (25 Angstrom) thick; it alternates from layer to layer between a parallel and a perpendicular arrangement with respect to the surface. (Edited author abstract) 17 refs.

Theodorou, Doros N. (Univ of California, Berkeley, CA, USA). *Macromolecules* v 21 n 5 May 1988 p 1400-1410.

**082920 DYNAMIC LIGHT SCATTERING STUDY OF A 2311 BASE PAIR DNA RESTRICTION FRAGMENT.** Dynamic light scattering time correlation functions from a solution of monodisperse, blunt-ended 2311 base pair DNA restriction fragment were measured at 20°C, in 100 mM NaCl, 10 mM Tris-HCl, and 1 mM EDTA (pH 8) at DNA concentrations ranging from 90 to 450 µg/mL. The correlation functions were analyzed by using CONTIN, a constrained inverse Laplace transform program. At scattering angles of 16° and 22° the correlation functions are consistent with single exponential decays representing the translational motion of the DNA. (Edited author abstract) 59 refs.

**082921 STUDY OF THE INTERACTION IN THE SYSTEMS CELLULOSE NITRATES-URETHANE RUBBERS.** DTA, X-ray diffraction and IR spectroscopy have been used to study the changes in the crystalline structure of polymers and the intermolecular interactions

in combined composites of cellulose nitrates with urethane rubbers. The value of the energy of the new system of hydrogen bonds between the C=O groups of the rubbers and the OH groups of cellulose nitrate has been determined. A correlation between the physicochemical characteristics of the combined systems and their structure and the character of the intermolecular interactions is demonstrated. (Author abstract) 7 refs.

Kostochko, A.V. (Kirov Chemic-Technological Inst, Kazan, USSR); Vasil'eva, G.A.; Maklakova, L.N.; Kuleznev, V.N. *Polym Sci USSR* v 29 n 2 Feb 1987 p 269-274.

**082922 <sup>13</sup>C NMR STUDY OF THE STRUCTURE OF POLYVINYL METHYL DI(ALKOXY) SILANES.** The present work explores by the <sup>13</sup>C NMR method the structure of polyvinylmethyl di(methoxy)silane, polyvinylmethyl di(propox)silane and polyvinylmethyl di(isopropox)silane in order to study the general patterns of polymerization of vinyl and the influence of the structure of the alkoxy substituent on the structure of the polymer. The rate of detachment of hydrogen from the α-carbon atom of the alkoxy group in the series OCH<sub>3</sub>, OCH<sub>2</sub>CH<sub>2</sub>CH<sub>3</sub> and OCH(CH<sub>3</sub>)<sub>2</sub>. It is found that the polymers studied represent extremely branched systems in which the centres of branching are the silicon atoms via two alkoxy groups and additionally each alkoxy group. (Edited author abstract) 10 refs.

Lavrukhin, A.D. (USSR Acad of Sciences, USSR); Strelkova, T.V.; Chernyavskaya, N.A.; Zhdanov, A.A. *Polym Sci USSR* v 29 n 2 Feb 1987 p 299-310.

**082923 CHARACTERIZATION OF THE CROSS-LINKED STRUCTURE OF HYDROGELS.** The theoretical study of a hydrogel network has the purpose of revealing the structure and configuration of its chains by use of appropriate theoretical models. The knowledge of the cross-linking density (in other words the effective number of cross-linked subunits,  $v_e$  and/or the number average molecular weight between cross-links,  $M_c$ ) is of great importance because of its effect on the mechanical and physical properties of the produced materials and their behavior in practical applications. In order to determine the cross-linking density of a hydrogel, use is made of mainly two theories, the equilibrium swelling theory and the rubber elasticity theory. The published literature in these areas is voluminous. Therefore, in this chapter we have taken more of a tutorial approach instead of reviewing all the existing literature. As for the methods of analysis, we concentrate only on references discussing the structural analysis of biomedical, especially hydrophilic, swollen networks. 38 refs.

**082928 A STUDY ON CHANGE OF FIBER STRUCTURES CAUSED BY PLASMA ACTION.** The degree of change of fibre structure due to plasma etching was studied. Various methods, including DSC, X-ray diffraction, ESCA and IR were employed, birefringence and wettability of the fibres were also studied. The degree of crystallization and orientation of the fibres were altered by plasma etching action. Differences in atom groupings within the fibres were observed, the water absorption property of the fibres increased. The authors investigated the character of both surfaces of the film which had been subjected to the plasma etching action from one side and also that of the film underneath, and concluded that the surface as well as the bulk of the fiber were affected by plasma action. It is suggested that the properties of the bulk fiber were influenced mainly by radiation of ultraviolet light. (Edited author abstract). 7 Refs.

**082929 APPLICATION OF SCALING TO THE STUDY OF POLYMERS AT INTERFACES.** The structure of polymer solutions at interfaces has been the object of intensive study: scaling analysis has provided many theoretical results. We present a survey of the work initiated by de Gennes and Alexander, and followed by Eisenriegler, Kremer and Binder using the magnetic analog. We compare the surface multicritical state at absorption edge to the bulk tricritical state at the Flory temperature. We give some of the detailed results obtained in Saclay. From the experimental point of view, test of scaling is given by the molecular weight dependences of the observables. However, more recently, deeper insight

has been gained by use of neutron scattering techniques developed by the Saclay Group. (Author abstract). 30 Refs.

**082930 PARTIAL CHARACTERIZATION OF THE STRUCTURE OF CRYSTALLINE POLYMER MOLDINGS.** Thermal and flow gradients present during thick polymer molding processes can produce layered structures through the thickness which vary in crystallinity, orientation, and axiality. Such structural complexity is difficult, expensive, and time consuming to characterize and presently impossible to predict. In order to overcome these problems emphasis in our laboratory has been directed toward the development of rapid, nondestructive techniques for the quantitative characterization of the structure of thick polymer samples. This includes the characterization of the average structure, the surface structure, and the internal layer structure. The present paper discusses some of these techniques and illustrates their application. (Author abstract). 12 Refs.

**082931 CONFORMATION AND ELECTRONIC STRUCTURE OF HETEROCYCLIC RING CHAIN POLYMERS.** A theoretical study is presented of the conformation and electronic properties of the polypyrrole, polythiophene and polyfuran chain polymer systems. These results are compared with experimental results and other theoretical studies, as well as with our previous model studies indicating the importance of the heteroatom in the  $\pi$ -band structure of these systems. The studies were performed in two steps. First, the authors calculated geometries for the three polymers using a semiempirical technique well known for its usefulness in predicting the bond lengths of organic systems. Second, they calculated the band structure and total energies of infinite single-chain polymers using the geometries calculated in the first step. (Edited author abstract). 34 Refs.

**082932 MODELLING NETWORK CLUSTERS OF FINITE SIZE. EVALUATION OF REACTIVITY, SPATIAL FORM AND TOPOLOGICAL STRUCTURE.** A model of the gradual formation of branched and network statistical macromolecules is proposed and clusters consisting of 50 elementary units are modelled by the Monte Carlo method. Information is obtained on the reactivity, form and topology of the clusters formed from units with different functionality. It is shown that increase in the fraction of bifunctional units lessen reactivity, increases the asymmetry of form and looseness, reduces the crosslinkage of the macromolecule and raises the heterogeneity of the cycles. (Author abstract). 23 Refs.

**082933 TWO-DIMENSIONAL PROPERTIES OF SUFACANT-LIKE POLYMER MONOLAYERS.** A functional polymer monolayer at an air/water interface has been studied systematically by substituting a hydrophobic backbone with a hydrophilic moiety (OH) by measuring the surface pressure as a function of surface concentration for different molecular weight polymers. The characteristic scaling exponent ( $\nu$ ) estimated from the isotherms and the overlap surface concentration suggests that the air/water interface becomes a better solvent as the amount of hydrophilic functional groups is increased. Also, the isotherms show that the area per polymer molecule increases with increasing amounts of OH groups. The surface occupied area per OH group ( $\sigma_{\text{OH}}$ ) is estimated with the ideal gas law at a dilute surface concentration. The results show that the  $\sigma_{\text{OH}}$  is a minimum at the same

substitution level at which the reduction of water surface tension is a maximum. (Edited author abstract). 7 Refs.

**082934 ANALYSIS OF CHEMICAL STRUCTURES OF ISOCYANURATE-OXAZOLIDONE RESINS BY INFRARED ABSORPTION SPECTROSCOPY.** Isocyanurate-oxazolidone resins were prepared from 2,4-tolylene diisocyanate (TDI) and 2,2-bis[(2,3-epoxypropylene)phenyl]propane (BPAGE) using N-methylmorpholine as a catalyst. Model polymers containing isocyanurate, oxazolidone, and uretidindione rings were prepared from TDI, diphenylmethane diisocyanate (MDI), triphenyl isocyanurate and BPAGE in order to form calibration curves for infrared spectrum. Composition of hetero rings in the cured product varied with curing temperature, time, and compound ratio. Isocyanate groups changed mainly to isocyanurate rings with ca. 20 mol% of the groups becoming oxazolidone rings. Product contents of uretidindione rings were less than 6 mol%. Reaction routes were analyzed from conversion ratios. (Edited author abstract). 25 Refs. In Japanese.

**082935 THERMODYNAMIC BASE FOR THE STRESS ACTIVATED PHASE TRANSITION DEFORMATION MODEL.** The three essential factors of the Juska-Harrison stress activated phase transition (SAPT) deformation model are analyzed. Based on the concept of 'mechanical melting', a formula for the theoretical melting stress is derived from thermodynamics. A comparison of experimental and calculated results for a number of polymers shows that the strain energy is high enough to induce isothermal 'mechanical melting' during extension, and the observed yield stress has the same order of magnitude as the theoretical melting stress. (Author abstract). 19 Refs.

**082937 MESOGENIC STRUCTURES AND CHARGE-TRANSFER REACTIONS IN POLY(ETHYLENE OXIDE) COMPLEXES.** After discussion of a schematic model for the crystalline phases of some poly(ethylene oxide) (PEO)-Na<sup>+</sup> complexes with organic anions, three types of material are discussed. Complexes of sodium salts of organic acids substituted by hydrophobic groups are deposited from methanol as macrodomains of uniaxially oriented material; these rearrange to microdomain morphologies on heating above ca. 60°C. Similar anions substituted by polar groups form spherulitic complexes or they rearrange thermotropically to microdomain structures. (Edited author abstract) 18 refs.

**082938 SWOBODNA ENERGIA POWIERZCHNIOWA NIEKTORYCH POLIMEROW.** [Free Surface Energy of Some Polymers]. The wetting contact angle in the systems polymer-water drop-air and polymer-methylene iodide drop-air has been measured for PTFE, PE, PET, PMMA, PVC, PA, PP and PA 6. Using the wetting angle values obtained, literature data of the components of the surface tension of water and measured by values of components of surface tension of methylene iodide, the dispersion and no-dispersion components of the surface free energy have been calculated for the above mentioned polymers on the basis of modified Girifalco-Good-Fowkes-Young equation. It has been found that the free surface energy of Polish-made polymers is practically similar to that of the corresponding foreign-made polymers. (Edited author abstract) In Polish. 17 refs.

**082940 SURFACE TENSION OF POLYTRIFLUOROPROPYLMETHYLSILOXANE.** Surface tension studies of the most common fluorosilicone, poly(3,3,3-trifluoropropylmethylsiloxane) (PTFPM), give unexpected results. Compared to polydimethylsiloxane (PDMS) the liquid surface tension is higher, the critical surface tension of wetting similar, and the solid surface tension, determined by water and methylene iodide contact angles and the method of D.K. Owens and R.C. Wendt, considerably lower. As the outermost surface of the lowest energy materials are comprised of close-packed perfluoromethyl groups and as a flexible polymer backbone should aid in the adoption of the lowest surface energy configuration, fluorosilicones could in principle be the lowest surface energy polymers. (Edited author abstract) 16 refs.

**082942 HYDROGELS FOR BLOOD CONTACT.** In this chapter, the most relevant issue is the surface, and the interaction of components of blood with the surface. The interior is, or should be, inaccessible to the macromolecular components of plasma and to all the cells (red cells, white cells, platelets). Therefore, we consider hydrogels in a revised sense for purposes of discussion of blood contact: a hydrogel presents a surface layer of bound molecules which by reason of their chemical nature hold a large fraction of water, in which the molecules are predominantly in an amorphous, water-solvated state, and in which the thickness of the layer is of the order of 30 Å minimum up to any indefinitely higher limit. In the chapter, the properties of blood-contacting hydrogels not having the anticoagulant heparin will be discussed. 89 refs.

**082943 STUDY OF SURFACE DYNAMICS OF POLYMERS. II. INVESTIGATION BY PLASMA SURFACE IMPLANTATION OF FLUORINE-CONTAINING MOIETIES.** Macromolecules at the surface of a polymeric solid have considerable mobility, and the specific arrangement of functional groups of macromolecules at the surface is dictated by the environmental conditions in which the surface is placed. Consequently, the change of environmental conditions, such as immersion in water or placement in a biological surrounding, could cause a considerable degree of change in the surface characteristics of a polymer from those evaluated in the laboratory against ambient air. The mobile nature of a polymer surface can be investigated by surface-implanting fluorine-containing moieties, mainly  $-\text{CF}_3$ , by the plasma implantation technique and following the disappearance and reappearance of fluorine atoms on the surface. The disappearance rates (based on the immersion time in water at room temperature) of ESCA  $\text{F}_{1s}$  signals, the decay rates of (advancing) contact angle of water, and the recovery of these values on heat treatment of water-immersed samples were measured as a function of crystallinity of polymer samples (at three levels of crystallinity) for poly(ethylene terephthalate) and nylon 6. (Author abstract). 17 refs.

**082946 RECENT ADVANCES IN ION AND ELECTRON SPECTROSCOPY OF POLYMER SURFACES.** The structure of microdomains and bonding at

multicomponent polymer material interfaces has been studied using a variety of surface sensitive spectroscopic techniques. In the author's laboratory, low energy ion scattering spectroscopy (ISS) and static secondary ion mass spectrometry (SIMS) serve to complement results from angular dependent X-ray photoelectron spectroscopy (XPS or ESCA), Fourier transform infrared (FTIR) with attenuated total reflectance (ATR) sampling and SEM techniques to provide a quantitative picture of the relationships between structure, bonding, morphology and microdomain formation in near surface regions of polymer systems. The added surface sensitivity of ISS can yield quantitative information at a sampling depth of 3-5 Å, which, with ESCA and FTIR analysis yields a 'nondestructive' depth profile of domain formation in copolymer and blend systems. These studies are illustrated with results from siloxane and siloxane/polycarbonate copolymer systems, where a complete picture of surface domain formation and morphology as a function of composition and polymer crystallinity has been developed. 32 refs.

**082947 PHOTO-MODIFICATION OF POLYMER SURFACE BY THE USE OF PHOTO-FRIES REARRANGEMENT AND PHOTO-OXIDATION AND APPLICATIONS.** It is possible to introduce pendant phenol groups on polymer chains by photo-Fries rearrangement of the pendant phenyl ester groups. These phenol groups are expected to be available as functional groups for dyeing polymer films. Copolymers of phenyl methacrylate (PMA) or S-phenyl thiomethacrylate (SPMA) with methyl methacrylate (MMA) (or styrene (St)) were prepared and their photoreactions were investigated. The functional groups which were produced by the photo-oxidation of SPMA units were deduced to play an important role in the dyeing. (Edited author abstract) In Japanese. 10 refs.

**082949 SURFACE MODIFICATION OF POLYMERS. I. VAPOR PHASE PHOTOGRAFTING WITH ACRYLIC ACID.** Surfaces of low density polyethylene, high density polyethylene, and polystyrene have been modified by grafting with acrylic acid. Benzophenone and acrylic acid in the vapor phase were UV-irradiated in the presence of a polymer substrate. Grafting with acrylic acid took place in a thin layer on the surface, thus increasing the wettability of the polymer. After 5 min of irradiation, the contact angle against water had decreased to 20° for polystyrene and 50° for the polyethylene samples. ESCA measurements on samples irradiated for 5 min showed a 90% poly(acrylic acid) coverage of the surface for polystyrene, 63% for low density polyethylene, and 56% for high density polyethylene. (Edited author abstract). 17 refs.

**082950 DETERMINATION OF SURFACE FREE**

**ENERGY COMPONENTS OF POLYMERS FROM CONTACT ANGLE DATA USING NONLINEAR PROGRAMMING METHODS.** A nonlinear method was applied to determine the surface free energy components  $\gamma_{\text{Psv}}$  and  $\gamma_{\text{dsv}}$  of ethylene-vinyl acetate and ethylene-vinyl alcohol copolymers from contact angle data by using the geometric-mean approximation. With this method, the 'actual' surface free energy components of the probe liquids,  $\gamma_{\text{PLV}}$  and  $\gamma_{\text{dLV}}$ , which reflect the fullest extent of liquid-polymer interactions and the interaction parameters,  $\Phi$ , were also simultaneously determined. The critical surface free energy  $\gamma_c$  of the copolymers was calculated from  $\Phi_{\text{av}}$  values by using Good's equation. (Author abstract). 13 refs.

**082952 DIE SWELL RESPONSE OF SEVERAL POLYMERS AND CARBON BLACK TYPES.** One of the major problems associated with the extrusion process is, as the extruded tread exits from the extruder die, the tread will normally shrink in length and increase in cross-sectional area. This increase in cross-sectional area is known as die swell. A number of evaluations were conducted to determine the extent and direction that die swell will be moved by such factors as black and polymer type, extruder equipment and operating conditions. Die swell was influenced by such variables as carbon black structure, black loading, oil level, polymer type, degree of mixing, extruder temperature, and work on the black during manufacturing. (Edited author abstract) 10 refs.

Wilder, C.R. (Phillips Petroleum Co). *Rubber World* v 197 n 1 Oct 1987 p 18-19, 21-22, 24-26.

**082953 SWELLING AND SORPTION IN POLYMER-CO<sub>2</sub> MIXTURES AT ELEVATED PRESSURES.** Experimental data on gas sorption and polymer swelling in glassy polymer-gas systems at elevated pressures are presented for CO<sub>2</sub> with polycarbonate, poly(methyl methacrylate), and polystyrene over a range of temperatures from 33 to 65°C and pressures up to 100 atm. The swelling and sorption behavior were found to depend on the occurrence of a glass transition for the polymer induced by the sorption of CO<sub>2</sub>. Two distinct types of swelling and sorption isotherms were measured. One isotherm is characterized by swelling and sorption that reach limiting values at elevated pressures. The other isotherm is characterized by swelling and sorption that continue to increase with pressure and a pressure effect on swelling that is somewhat greater than the effect of pressure on sorption. Glass transition pressures estimated from the experimental results for polystyrene with CO<sub>2</sub>

are used to obtain the relationship between  $\text{CO}_2$  solubility and the glass transition temperature for the polymer. (Edited author abstract) 33 refs.

**082954 ELASTIC PROPERTIES OF SWOLLEN REAL POLYMER NETWORKS.** In this paper a new set of stress-strain relations (uniaxial, equi-biaxial, uniaxial extensions and pure shear) for swollen networks were presented. They are derived from the molecular theory of rubber elasticity with constraints of junctions and trapped entanglements and with crosslinks, trapped entanglements and carbon black-polymer interactions. They succeeded in relating the elastic equation of state to the volume fraction of polymer  $V_2$  in swollen networks by three molecular parameters  $C_1$ ,  $C_2$  and  $C_3$ . The relation of stress-strain for uniaxial extension was verified by experiments. It is shown that this relation can successfully predict the dependence of  $V_2$  on the  $C_1$ ,  $C_2$  and  $C_3$ , and the contribution of modulus for swollen networks from the trapped entanglement. It shows that role of entanglements can only approach to a limited value, never to zero. (Edited author abstract) 10 refs.

**082956 HYDROGELS IN MEDICINE AND PHARMACY (V 1, FUNDAMENTALS; V 2, POLYMERS; V 3, PROPERTIES AND APPLICATIONS).** This set of three volumes contains twenty chapters about the chemistry, physics and applications of hydrogels. Some of the topics covered in Vol 1 are: preparation and structure of hydrogels; hydrogel surfaces; and immobilization of biomolecules and cells within hydrogels. Vol 2 is concerned with the structure and function of the medically important hydrogels: they are polyvinylalcohol; polyhydroxyethyl-methacrylate; polyethylene oxide; and cellulose. Vol 3 describes biomedical and pharmaceutical applications of hydrogels. Some of the topics covered are: blood compatibility; heparinized surfaces; contact lenses; artificial tendons; and bioerodible gels.

Peppas, Nikolaos A. (Ed.) (Purdue Univ, West Lafayette, IN, USA). *Hydrogels in Med and Pharm* Publ by CRC Press Inc, Boca Raton, FL, USA, 1986 3v.

**082957 IMMOBILIZATION OF BIOMOLECULES AND CELLS ON AND WITHIN SYNTHETIC POLYMERIC HYDROGELS.** The study and application of immobilized biologically active molecules and cells have become increasingly important endeavors in both medicine and industry. Biomolecules and cells can be immobilized on and within many different supports using a variety of techniques. Hydrogels have some properties which make them particularly suitable for this purpose. A hydrogel can be defined as a polymeric material which exhibits the ability to swell in water and retain a significant fraction of water within its structure without dissolving. Small hydrophilic molecules can readily diffuse through hydrogels. Hydrogels exhibit good tissue biocompatibility and may interact less strongly with immobilized species than more hydrophobic materials. Thus molecules and cells immobilized on or within hydrogels may be more likely to retain their biological activity for longer periods

of time. Hydrogels may also have a large number of polar reactive sites on which biomolecules and cells can be immobilized by relatively simple chemistries. 191 refs.

Gombotz, Wayne R. (Univ of Washington, Seattle, WA, USA); Hoffman, Allan S. *Hydrogels in Med and Pharm* Publ by CRC Press Inc, Boca Raton, FL, USA, 1986 v 1, p 95-126.

**082958 EQUILIBRIUM SWOLLEN HYDROGELS IN CONTROLLED RELEASE APPLICATIONS.** Controlled release systems represent a relatively new development that evolved out of a continuing need to prolong and better control drug administration. In conventional drug delivery modes such as a spray, an injection, or the taking of a pill, each time a person takes medicine, the drug concentration in the blood rises, peaks, and then declines. Since each drug has a therapeutic range above which it is toxic and below which it is ineffective, the plasma drug concentration in any patient at a particular time depends on compliance with the prescribed routine. This is particularly problematic if the toxic and minimum effective levels are close together. The goal of a controlled release system is to maintain the drug concentration between these two levels for a prolonged time using a single dosage form. 82 refs.

Kost, Joseph (Ben Gurion Univ, Beer Sheva, Isr); Langer, Robert. *Hydrogels in Med and Pharm* Publ by CRC Press Inc, Boca Raton, FL, USA, 1986 v 3, p 95-108.

**082959 DYNAMICALLY SWELLING HYDROGELS IN CONTROLLED RELEASE APPLICATIONS.** The physical properties of hydrogels make them attractive for controlled release applications. Their biocompatibility allows them to be considered for medical or pharmaceutical applications and their hydrophilicity can impart desirable release characteristics to controlled and sustained release formulation. This chapter is concerned primarily with materials which are in a dry or glassy state before being placed at the release site, whether this site is the buccal, gastric, nasal, or intestinal area, or a subdermal location. This allows the designer to take advantage of the swelling properties of the material and to control the rate of active release. 123 refs.

Peppas, Nikolaos A. (Purdue Univ, West Lafayette, IN, USA); Korsmeyer, Richard W. *Hydrogels in Med and Pharm* Publ by CRC Press Inc, Boca Raton, FL, USA, 1986 v 3, p 109-136.

**082960 BIOADHESIVE HYDROGELS.** A hydrogel is defined as a polymeric material which has the ability to swell in water without dissolving, and to retain water within its structure. There are a variety of synthetic and natural polymers that can be included in this definition. In this chapter, attention will be focused on particular hydrogels possessing bioadhesive properties. It is appropriate to begin this discussion with definitions of bioadhesion and bioadhesive. One distinctive feature of bioadhesion is that adhesion almost always occurs in the presence of water. In contrast to numerous studies on adhesion in artificial systems, where both adhesive and adherend are nonbiological materials, there are very few useful research surfaces. For this reason, bioadhesion has been described from a phenomenological point of view, almost exclusively, rather than from a molecular perspective. 128 refs.

**082961 SYNTHESIS AND CHARACTERIZATION OF CONDUCTING POLYPYRROLE-CONTAINING IRON COMPLEXES.** Electrochemical or chemical oxidation of pyrrole-containing complex anions of iron cyanide or iron chloride results in the formation of films or powders of conducting polypyrroles. Freshly prepared films exhibit an additional IR band at ca 1630-1640  $\text{cm}^{-1}$ , slowly disappearing in air and not observed in previous studies of polypyrrole-based systems. It is possible that this new band is associated with the existence of a C=N bond in dehydrogenated pyrrole rings which are transformed into regular pyrrole rings, probably due to the protonation reaction occurring in air and simultaneous bond rearrangement. The polypyrrole structure favors the presence of  $\text{Fe}(\text{CN})_6^{4-}$  over  $\text{Fe}(\text{CN})_6^{3-}$  since the former is the only iron species detected by Moessbauer spectroscopy in electrochemically prepared samples. (Edited author abstract) 19 refs.

**082963 LIVING CARBOCATIONIC POLYMERIZATION - V. LINEAR TELECHELIC POLYISOBUTYLENES BY BIFUNCTIONAL INITIATORS.** The synthesis of  $\alpha,\omega$ -di-1-chloropolyisobutylene has been accomplished by living polymerization using aliphatic and aromatic tert-diacetate initiators in conjunction with  $\text{BCl}_3$  coinitiator in various solvents in the  $-20$  to  $-70^\circ\text{C}$  range. The living nature of the polymerizations was demonstrated with the instantaneous initiators 2,4,4,6-tetramethylheptane-2,6-diacetate and 1,4-di(2-propyl-2-acetate)-benzene by linear  $M_n$  versus amount of PIB formed ( $W_{PIB}$ ) plots starting at the origin. The formation of undesirable indanyl structures that arise with the aromatic initiator can be suppressed by decreasing the temperature and the polarity of the polymerization medium (i.e., by using  $\text{CH}_2\text{Cl}_2/\text{n-C}_6\text{H}_{14}$  mixtures). (Edited author abstract) 18 refs.

**082964 SYNTHESIS AND CHARACTERIZATION OF NEW POLYETHERAMIDES.** Polyetheramides (PEAs) are prepared by polycondensation of N,N'-diacetyl-o-tolidide with Bisphenol A, C, or F, phenolphthalein, resorcinol, catechol, hydroquinone, or 1,5- or 2,7-dihydroxynaphthalene or ethylene, butylene, propylene, diethylene, or triethylene glycol. The fusible and soluble oligomers are characterized. An attempt is made to bring out the relationship between various properties of PEAs and their structures. (Author abstract) 11 refs.

**082965 CHEMOTHERAPEUTIC POLYMER: XVII. THE SYNTHESIS AND ANTITUMOR ACTIVITY OF POLYPHOSPHATES CONTAINING BOTH NUCLEIC ACID BASE AND NITROGEN MUSTARD.** Seven new polyphosphates containing both nucleic acid base and nitrogen mustard were prepared by reacting the monomers i.e., 1,3-dihydroxyalkyl-5-fluorouracil, 1,3-dihydroxyalkyluracil and 1,3-dihydroxyalkylthymine with N,N-bis(2-chloroethyl)phosphoramide dichloride. The monomers and polymers were characterized by <sup>1</sup>H-NMR, IR spectra and elemental analysis. All of the polymers obtained are soluble in water. The antitumor activity of some of these polymers were tested against Ehrlich Ascites in mice. The results showed that the polyphosphates containing both 5-fluorouracil and nitrogen mustard exhibit lower toxicity and higher antitumor activity. The inhibition ratio of the polymer is 66%. (Edited author abstract) 5 refs.

**082967 SYNTHESIS AND CHARACTERIZATION OF POLYMER DERIVATIVES OF cis-PLATINUM COMPLEXES.** Cis-platinum complexes used as antitumor drugs were attached onto preformed polymers to reduce the toxicity. Either alternating copolymer of styrene and maleic anhydride (CPSMA) or polyacrylic acid (PAA) is readily dissolved in alkaline solution. The cis-platinum complexes are easily converted into water soluble species when treated by silver nitrate in water. The expected products could be obtained when the two aqueous solutions were brought together. The products were characterized by elementary analysis, IR and XPS. The polymer derivatives could exchange ligands with nucleophilic groups in biological environment and also exhibit antineoplastic activity. (Author abstract) 10 refs.

**082968 STUDY OF SELF-SPLITTING WATER SOLUBLE IONOGENIC POLYMERS.** Water-soluble readily self-splitting ionogenic polymers may be created through the synthesis of macromolecules which along with ester groups susceptible to hydrolytic splitting also contain groups that are capable of catalyzing this process. Polymers of this type include polyaminoesters based on primary and secondary aliphatic diamines and glycol diacrylates. The polyaddition reaction is carried out in an aqueous medium, as a heterogeneous process, with cooling (−5 to −10°) in air for 15-30 min. In this way polyaminoesters are obtained in quantitative yields. A study of the hydrolytic stability of polyaminoesters showed that the initial rate of hydrolysis of the polymers largely depends on the pH<sub>0</sub> of the medium. (Edited author abstract) 5 refs.

**082969 CHEMICAL INDIVIDUALS AND UNIT HETEROGENEITY OF POLYMERS.** The concepts of the chemical individual and unit heterogeneity of polymers are considered. It is shown that polymers represent mixtures of macromolecules of different size and composition and are, therefore, not chemical individuals. How-

ever, each such mixture consists of a large number of chemical individuals which are polymer homologues and contain unit heterogeneous chains. The unit heterogeneity of polymers is determined by the presence of secondary reactions and the content of stable isotopes statistically distributed over the chain of the macromolecule. The processes of polymer synthesis by polymerization, polycondensation and modification represent complexes of diverse reactions determining the advent of unit heterogeneity of the polymers. (Edited author abstract) 18 refs.

**082973 SYNTHESIS AND CHARACTERIZATION OF BIPHASIC LIQUID CRYSTALLINE POLYSILOXANES CONTAINING 4-UNDECANYLOXY-4'-CYANOBIPHENYL SIDE-GROUPS.** The synthesis and characterization of liquid crystalline polysiloxanes and copolysiloxanes containing 4-undecanyloxy-4'-cyanobiphenyl side-groups is presented. The polysiloxane presents a single glass transition temperature followed by a S<sub>c</sub> and a S<sub>a</sub> mesophase. Copolysiloxanes presenting around 50% weight fraction of side-groups exhibit two

glass transition temperatures i.e., one due to the independent motion of the main chain and the other due to the cooperative but independent motion of the side groups, and in addition to the S<sub>c</sub> and S<sub>a</sub> phases exhibited by the homopolymer, present also side-chain crystallization. **082976 QUASILIVING CARBOCATIONIC POLYMERIZATION. XVII. SYNTHESIS OF POLY[STYRENE-β-ISOBUTYLENE-β-STYRENE].** Poly(styrene-β-isobutylene-β-styrene) has been synthesized by sequential carbocationic polymerization under quasiliving conditions at −90°C. The quasiliving synthesis was effected by first continuously and slowly condensing gaseous isobutylene (IB) to a bifunctional initiating system (p-dicumyl chloride/TiCl<sub>4</sub>) dissolved in a hexane-methylene chloride (60:40 v/v) mixture. After the quasiliving polyisobutylene (PIB) sequence had reached a desired molecular weight, styrene (St) was continuously and slowly added to produce the polystyrene (PSt) sequence. The products consisted of the target triblock. (Edited author abstract) 12 refs.

**082979 POLYMERIZATION OF N-METHYLPYRROLE WITH BIS-TRIAZOLINEDIONES VIA ELECTROPHILIC AROMATIC SUBSTITUTION.** The reaction of N-methylpyrrole with 4-substituted-1,2,4-triazoline-3,5-diones (4R-TDs), i.e., MeTD (4-methylsubstituted) and PhTD (4-phenyl substituted), at room temperature without use of any catalyst was investigated. The reaction is instantaneous and leads to the formation of a 2:1 adduct in high yield, with substitution occurring at the 2 and 5 positions of the pyrrole moiety via electrophilic aromatic substitution. These compounds were fully characterized by IR,  $^{13}C$ -NMR,  $^1H$ -NMR, and elemental analysis, and were used as model compounds for the polymerization reaction. The reaction of bis-triazolinediones with N-methylpyrrole was carried out in dimethylformamide at room temperature. The reactions are fast and give novel polymer structures. Some structural characterization and physical properties of these new polymers are reported. (Author abstract) 20 refs.

**082980 SYNTHESIS AND PROPERTIES OF POLY(AROMATIC KETONES).** W.H. Bonner reported the first preparation of poly(aromatic ketones) (PAK) by aluminum chloridocatalyzed acylation of diphenyl ether with aromatic diacid chlorides. These were low molecular weight materials because of solubility limitations. In the intervening years, significant progress has been made in synthetic methodology, and now a large variety of structures is available for study. Unlike poly(aryl sulfones) which are typically amorphous, most PAK's exhibit partial crystallinity, usually with melting points above 300°C. Like the sulfones, the ketone polymers possess high thermal stability and exhibit excellent electrical and mechanical properties. The development of this polymer family is the subject of this review. 62 refs.

**082988 PREPARATION OF POLY(MALIC ACID) AND ITS ESTER DERIVATIVES BY DIRECT POLYCONDENSATION OF MALIC ACID AND  $\beta$ -ETHYL MALATE.** Direct polycondensations of d,l- and l-malic acids and d,l, $\beta$ -ethyl malate were studied. The dehydrative condensation of d,l-malic acid occurred at 110 approximately 140°C in vacuo to give poly( $\alpha$ ,  $\beta$ -malic acid) with a molecular weight of ca. 2000 (by GPC). This polymer had a random sequence of both  $\alpha$ - and  $\beta$ -type units in equal ratio. The molecular weight, however, did not become higher owing to irreversible depolymerization. By similar dehydrative polycondensation of d,l, $\beta$ -ethyl malate, poly( $\beta$ -ethyl malate) with a molecular weight of ca.1300 was produced. The copolycondensation of d,l-malic acid and d,l, $\beta$ -ethyl malate was also investigated to prepare malic acid- $\beta$ -ethyl malate copolymer. In addition, hydrolysis of poly( $\alpha$ ,  $\beta$ -malic acid) was examined in deuterium oxide by  $^1H$  NMR spectroscopy. (Author abstract) 27 refs. In Japanese.

**082992 STUDIES OF POLY(ortho-ACYLSTYRENES). I. SYNTHESIS AND CHARACTERIZATION.** The syntheses of a number of *o*-acylstyrene (*o*-acetyl through *o*-hexanoyl) have been described. Polymerizations were carried out radically at 80°C under high vacuum. While all polymerizations conform to the usual free radical kinetic scheme, rates are sensitive to the nature of the acyl substituent, and this has been ascribed to steric effects, the bulky substituents adjacent to the propagating radicals inhibiting the approach of monomer. Molecular weight and polydispersity data indicate that both combination and disproportionation occur during terminations. UV spectra consist of two absorptions associated with  $n \rightarrow \pi^*$  and  $\pi \rightarrow \pi^*$  transitions. <sup>13</sup>C-NMR spectra have been analyzed and assignments made on the basis of spectral editing. The considerable variation of glass transition temperatures has been accounted for in terms of a combination of steric and dipolar interactions. (Author abstract) 20 refs.

**082994 GRAFTING OF PARTIALLY HYDROLYSED POLY(METHYL METHACRYLATE) ONTO MESYLATED CELLULOSE ACETATE.** A new synthetic route to cellulose graft polymers by nucleophilic displacement of mesylate groups from mesyl cellulose acetate (MCA) by the polystyrylcarboxylate anion has been recently reported by us. This approach to cellulosic graft polymers overcomes the drawbacks of the radical polymerization methods and allows for precise control of parameters such as the molecular weight and molecular weight distribution of the grafted side chains, higher

degree of substitution on the cellulose backbone, the number and nature of grafted side chains and overall better control and reproducibility of the grafting process. In this report, partially hydrolyzed poly(methyl methacrylate) was successfully grafted on to mesylated cellulose acetate in excellent yields by nucleophilic displacement of mesylate groups in less than 60 min at 75°C. (Author abstract) 10 refs.

**082995 LINEAR, SOLUBLE POLY(BISMETHYLENE HYDROQUINONE), A LADDER POLYMER: SYNTHESIS AND CHARACTERIZATION.** A route to prepare a soluble linear ladder of poly(bismethylene hydroquinone) was developed. 2,3,5,6-Tetramethylol hydroquinone was reacted with hydroquinone in sulfolane with acid catalysis. Gel formation was prevented by removing the water generated during the condensation, and by preventing oxidation of the polymer during reaction. Polymers with intrinsic viscosities as high as 5.0 were obtained; viscosity depended on the mole ratio of the starting materials and the reaction conditions. Polymer structure was characterized by Fourier transform infra-red spectroscopy, nuclear magnetic resonance spectroscopy, polarizing microscopy and X-ray diffraction. (Author abstract) 23 refs.

**082996 PRESENT TRENDS IN THE SYNTHESIS OF THERMOSTABLE POLYMERS BY POLYCONDENSATION METHODS. REVIEW.** A study was made of present-day trends in the development of polycondensation methods for the synthesis of thermostable heterocyclic polymers, in particular polybenzazoles and PIs. Subjects of major interest were catalytic methods that could be used for the synthesis of polybenzazoles and variants of these polymers by precipitative, and reduction methods, as well as by 'direct' polyheterocyclization. The study also covered complex reactions in the synthesis of polybenzazoles leading to 'ladder' polyheteroarylenes of the polyazoloquinazoline series. A promising trend in the development of PI chemistry has resulted in polynaphthylimides and their derivatives, viz. polynaphthylenebenzimidazoles. (Edited author abstract) 74 refs.

**082997 ELECTROCHEMICAL SYNTHESIS AND SPECTROSCOPIC STUDY OF POLY(3-ALKYLTHIENYLENES).** The class of poly(3-alkylthienylenes) [P3ATs] has been synthesized by an improved method of electrochemical polymerization carried out under a rigorously oxygen-free and moisture-free environment. Within this class, the highest conductivity (750 S/cm) was obtained for poly(3-methylthienylene). The P3ATs (carrying hydrocarbon chains with carbon numbers of four or more) also show relatively high conductivities ranging from about 1 to 10<sup>2</sup> S/cm. The P3ATs with relatively longer hydrocarbon chains show good solubility in various organic solvents and can be readily processed from solution both in the neutral and in the conducting (oxidized) form. (Edited author abstract) 21 refs.

**082998 CONFORMATION AND ELECTRONIC STRUCTURE OF POLY (3,4-DIISOPROPYLIDENECYCLOBUTENE), A CROSS-CONJUGATED CONDUCTIVE POLYMER.** It has been reported recently that poly(3,4-diisopropylidenecyclobutene) 1, synthesized by a novel olefin-metathesis route, can be oxidatively doped to yield materials with moderate conductivities. Theoretical studies reveal that, due to steric crowding, polymer 1 cannot achieve a planar, fully-conjugated structure in either its undoped or doped states. Rather, the structure consists of essentially orthog-

onal tetramethylhexatriene units. Such a structure is incompatible with conventional conduction mechanisms involving polarons or bipolarons. It is proposed that, instead, conduction involves intra- and/or inter-chain charge transfer. (Edited author abstract) 11 refs.

**082999 SYNTHESIS AND CONDUCTIVITY STUDIES OF POLY(2,5-DIMETHOXY-1,4-PHENYLENE VINYLENE).** Given the simplicity of preparation of high molecular weight PPV (poly(p-phenylene vinylene)) via the quinodimethane route and the ease of synthesis of the starting monomers, we chose to investigate the applicability of this route to the preparation of substituted PPV. We have prepared high molecular weight PDMPV (poly(2,5-dimethoxy-1,4-phenylene vinylene)) via a processable precursor polymer and report its unusual oxidative and reductive behavior. The conductivity and electrochemical potential versus doping level behavior for PDMPV was determined by in situ four-probe conductivity measurements recorded at intervals during electrochemical oxidation, and are presented. We have also found that PDMPV can be reversibly reduced (n-type doped) in an electrolyte of sodium tetraphenylborate in 2-methyltetrahydrofuran. In this case, sodium ions are inserted into the polymer. 11 refs.

**083002 SYNTHESIS AND BIOMEDICAL PROPERTIES OF POLY-[(ETHYLENE-VINYL ALCOHOL)-g-ACRYLAMIDE].** This paper deals with the graft copolymerization of acrylamide (AM) onto ethylene-vinyl alcohol copolymer (EVAL) film initiated by cerium(IV) ion. It was found that both the chemical and diffusion factors had influences on the graft reaction. The reaction was initiated on the surface and then penetrated inward as the grafting percentage was increased. The permeability of urea through the grafted EVAL film was improved compared to that of the original film as was the blood compatibility. (Author abstract) 18 refs.

**083003 REACTIONS AND POLYMERIZATION OF 1-TRITYL-4-VINYLMIDAZOLE.** 1-Trityl-4-vinylimidazole was prepared by direct tritylation of 4(5)-vinylimidazole and polymerized using a free radical initiator. Poly(1-trityl-4-vinylimidazole) was hydrolyzed

using aqueous acetic acid to give poly[4(5)-vinylimidazole]. The poly[4(5)-vinylimidazole], which was obtained from the hydrolysis of poly(1-trityl-4-vinylimidazole), was compared with poly [ prepared directly from 4(5)-vinylimidazole for differences in stereochemistry. The stereochemistry of both polymers was found to be similar by high-resolution NMR. Thus, the trityl does not influence the stereochemistry of poly [ . The reaction of 1-trityl-4-vinylimidazole with *n*-butyllithium gave 2-lithio-1-trityl-4-vinylimidazole. This intermediate was used to prepare 2-substituted 4(5)-vinylimidazoles, which are new monomers that can be polymerized using free radical initiators. (Author abstract) 5 refs.

**083004 SYNTHESIS OF POLY(1,3,4-OXADIAZOLES) BY DIRECT POLYCONDENSATION OF DICARBOXYLIC ACIDS WITH HYDRAZINE SULFATE USING PHOSPHORUS PENTOXIDE/METHANESULFONIC ACID AS CONDENSING AGENT AND SOLVENT.** A convenient method for the synthesis of poly(1,3,4-oxadiazole)s of high molecular weights has been developed. These polymers were prepared readily by the direct polycondensation of dicarboxylic acids with hydrazine sulfate (1) using phosphorus pentoxide/methanesulfonic acid (PPMA) as both a condensing agent and solvent. Polycondensation of aliphatic dicarboxylic acids with 1 proceeded even at room temperature and produced poly(1,3,4-oxadiazole)s with inherent viscosities up to 1.4 dL/g. The synthesis of aromatic poly(1,3,4-oxadiazole)s from aromatic dicarboxylic acids containing phenyl ether structures was carried out by a one-pot procedure because the preactivation of dicarboxylic acids was required. The synthesis of 2,5-disubstituted-1,3,4-oxadiazoles by the reaction of carboxylic acids with 1 in PPMA was studied to demonstrate the feasibility of the reaction for polymer formation. (Edited author abstract) 13 refs.

**083005 SYNTHESIS AND REACTIONS OF UNIFORM SIZE POLY(DIMETHYLSILOXANE) WITH VARIOUS REACTIVE END GROUPS.** The reaction of monofunctional living poly(dimethylsiloxane), poly(DMS), with dimethylchlorosilane (2), followed by the hydrosilylation of the polymer end SiH group with allyl alcohol was performed. The hydroxyl end group of poly(DMS) (4) thus obtained was subsequently converted to the tosylate ester group through treatment with tosyl chloride in the presence of 4-dimethylaminopyridine (DMAP). The tosylate ester end group of poly(DMS) (5) was found to initiate the cationic ring opening polymerization of 2-methyl-2-oxazoline (OXZ) to produce the poly(DMS)/poly(OXZ) block copolymer (7). (Author abstract) 16 refs.

**083006 FUNCTIONAL MONOMERS AND POLYMERS - CLVIII. ASYMMETRIC INCLUSION POLYMERIZATION OF CYCLIC DIENE MONOMERS IN A DEOXYCHOLIC ACID CANAL.** Asymmetric inclusion polymerization has become one of the most interesting subjects in this decade. In an asymmetric canal formed from a chiral host such as deoxycholic acid (DCA) or apocholic acid, polymerization reactions can be regulated by a host-guest relationship in size, shape, chirality, and polarity. In this communication we report the asymmetric inclusion polymerization of cyclic diene monomers in a DCA canal. Optically active poly(cyclodienes) were first obtained by inclusion polymerization via a radical mechanism, using DCA as a host molecule. 6 refs.

**083009 LINEAR POLYTHIOESTERS. XIII. PRODUCTS OF POLYCONDENSATION OF ISOMERIC Di(MERCAPTOMETHYL)-DIMETHYLBENZENES WITH ADIPOYL AND SEBACOYL CHLORIDES.** The synthesis of a new aliphatic-aromatic polythioesters obtained by polycondensation of 4,5-di(mercaptomethyl)-1,2-dimethylbenzene, 4, 6-di(mercaptomethyl)-1,3-dimethylbenzene and 2, 5-di(mercaptomethyl)-1,4-dimethylbenzene with adipoyl and sebacyl chloride is described. To define the optimal condition of the process, the polythioester from 2,5-di(mercaptomethyl)-1, 4-dimethylbenzene and sebacyl chloride was chosen as a model system and obtained by interfacial polycondensation as well as by low- and high-temperature solution polycondensation. The quality of the obtained polycondensates was estimated on the basis of values of the reduced viscosity and yield. The structure of the aliphatic-aromatic polythioesters was determined from elementary analysis, infrared spectra, and x-ray analysis. Some thermal, mechanical, electrical, and chemical properties as well as molecular weights of obtained polycondensates have been determined. (Edited author abstract) 8 refs.

**083010 POLYMERIZATION KINETICS OF POLYSILAZANE BY TRANSITION METAL CATALYZED DEHYDROCOUPLING REACTION.** Transition metal catalyzed polymerization of polysilazanes has been reported as one of potential routes to silicon nitride precursor synthesis. In this communication, we report a study of the polymerization kinetics of poly-*N*-methylsilazane (PNMS) catalyzed by Ru<sub>3</sub>(CO)<sub>12</sub>. The polymerization reaction of PNMS proceeds from oligosilazanes. This communication demonstrates the importance of molecular and structural characterization of the reacting medium to better understand the reaction mechanism of the polysilazane preceramic polymers. These characterization results will also serve as a database for establishing a

structure-property-processing relationship for better molecular design of inorganic and organometallic polymers. 6 refs.

**083011 SYNTHESIS OF FUNCTIONALIZED LINEAR POLY(DIVINYLBENZENE). III. SYNTHESIS OF POLYMERIC DELOCALIZED CARBANION OF POLY(DIVINYLBENZENE) AND ITS REACTIONS.** A polymeric delocalized carbanion of poly(divinylbenzene) [poly(DVB)](2) was obtained by the proton abstraction with alkyllithium from the acidic methine moieties (H<sub>A</sub>) of linear poly(DVB) (1), which was prepared by the polymerization of DVB initiated by acetyl perchlorate. The formation of polyanion 2 was confirmed by UV-visible spectroscopy (λ<sub>max</sub>=630 nm) and the reaction with methyl iodide to give methylated poly(DVB). Delocalized polyanion 2 reacted with various electrophilic reagents in THF at 60°C, to yield poly(DVB) derivatives having pendant trimethylsilyl, vinyl, vinyloxy, hydroxyl, and carboxyl groups. Proton abstraction with base and subsequent reactions with electrophiles were also studied with the linear unsaturated dimer of styrene (1,3-diphenyl-1-butene), as a model for poly(DVB) 1. **083013 PREPARATION OF POLYSILOXANES FROM SILICIC ACID. X. PREPARATION AND PROPERTIES OF ALLYLDIMETHYLSILYLATED SILICIC ACIDS.** In order to obtain polysiloxanes capable of forming a film, the preparation and properties of allyldimethylsilylated silicic acid was investigated. The reaction in variable molar ratios of allyldimethylchlorosilane to silicic acid gave partially silylated silicic acids with different degrees of silylation. They provided not only fibrous polysiloxanes but also films from concentrated polymer solutions. Spinnability and film formation depended on the solvent, degree of silylation, molecular weight, and allyl group. (Author abstract) 3 refs.

**083015 SYNTHESIS OF POLYMER MATERIALS BY LOW-ENERGY ELECTRON BEAMS: 5 EFFECTS OF PREPOLYMER MOLECULAR WEIGHT ON STRUCTURE AND PROPERTIES OF ELECTRON-BEAM-CURED GEL FILMS.** The effects of prepolymer molecular weight on the structure and properties of electron-beam-cured (EB-cured) gel films were investigated. The molecular weight of the urethane-acrylate prepolymer, which was synthesized by reaction of poly(butylene adipate) diol (PBAD), 4,4'-diphenylmethane diisocyanate (MDI) and 2-hydroxyethylacrylate (HEA), was varied between 1,450 and 3,200 by changing the molecular weight of PBAD. Above a prepolymer molecular weight of 2,700, the crystallinity arising from PBAD moieties decreased with decreasing molecular weight for both the prepolymer films and EB-cured gel films. Below a molecular weight of 1,700, these films had no crystallinity and gave an amorphous film. (Edited author abstract) 14 refs.

**083016 SYNTHESIS AND CHARACTERISATION OF POLY(ARYLENE SULPHIDES): PART 10. A COMPARATIVE EVALUATION OF THE THERMOANALYTICAL BEHAVIOUR AND CURING OF POLY(1,4-PHENYLENE SULPHIDE) AND COPOLYMERS CONTAINING 1,4-PHENYLENE SULPHIDE AND 2-METHYL-1,4-PHENYLENE SULPHIDE REPEAT UNITS.** Thermogravimetry, differential scanning calorimetry and curing studies were used to assess the viability of random and block copolymers comprising 1,4-phenylene sulphide and 2-methyl-1,4-phenylene sulfide repeat units as alternatives to poly(1,4-phenylene sulfide) (PPS). The properties of the copolymers are discussed critically and compared with those of the parent homopolymers PPS and poly(2-methyl-1,4-phenylene sulfide) (PMPS). The results suggest that (a) random copolymers with low PMPS contents would offer the best compromise between PPS and PMPS properties, and (b) more desirable physical properties might be achieved from systems containing a less reactive 2-substituted-1,4-phenylene sulfide comonomer repeat unit. (Author abstract) 20 refs.

**083017 SYNTHESIS AND REACTIONS OF POLYMERS WITH PHOTOACTIVE TERMINAL GROUP - 3. THE USE OF RADICAL PROMOTED CATIONIC POLYMERIZATION FOR THE SYNTHESIS OF POLY(n-BUTYL VINYLETHYL) WITH N-ACYL DIBENZ(b, f)AZEPINE TERMINAL UNITS.** The free radical promoted cationic polymerization of n-butyl vinyl-ether (BVE) was achieved by the thermal decomposition of N-[4,4'-azobis-(4-cyanopentanol)]-bis(dibenz(b, f)azepine (ADBA) in the presence of diphenyliodonium hexafluorophosphate ( $\text{Ph}_2\text{I}^+\text{PF}_6^-$ ) or silver hexafluorophosphate ( $\text{AgPF}_6$ ). Polymer samples prepared in the presence of  $\text{AgPF}_6$  contained a significant number of terminal dibenzazepine units. Chain extension via dimerization of the dibenzazepine units occurred upon irradiating these polymers with u.v. light ( $\lambda = 366 \text{ nm}$ ) in  $\text{CH}_2\text{Cl}_2$  solution containing a triplet sensitizer (benzophenone or benzil). (Edited author abstract) 9 refs.

**083020 PROTECTIVE GROUP SYNTHESIS OF POLY-N-HYDRO-(3,6-CARBAZOLYL).** Poly-N-trityl-(3,6-carbazolyl), PNTPMCZ, has been synthesized in pyridine solution using an activated nickel catalysts. 9-Trityl-3,6-dihydrocarbazole was polymerized and the triphenylmethyl group subsequently removed by acid hydrolysis. The N-protected monomer was made by a phase-transfer reaction employing 3,6-dihydrocarbazole, a benzotriethylammonium chloride catalyst, basic solution and triphenylmethyl chloride. A wide variety of N-substituents can be obtained in this way, allowing the molecular design of polycarbazolyls to be controlled. Poly-N-hydro-(3,6-carbazolyl), PNHCZ, obtained from PNTPMCZ, forms iodine complexes with conductivities of  $10^{-1} \text{ ohm}^{-1} \text{ cm}^{-1}$  at room temperature. The visible-near-i.r. spectra suggest that the same radical cations responsible for conductivity in poly-N-methyl-(3,6-carbazolyl) are present. (Edited author abstract) 14 refs.

**083022 SYNTHESIS OF POLYMER MATERIALS BY LOW ENERGY ELECTRON BEAM. III. EFFECTS OF POLYMERIZATION TEMPERATURE IN EB SOLID-STATE POLYMERIZATION OF SEMICRYSTALLINE URETHANE-ACRYLATE FILM.** In an electron beam (EB) polymerization of a urethane-acrylate prepolymer, the polymerization temperature greatly affected the structure and properties of the resulting gel film. Urethane-acrylate, which was synthe-

sized by the reaction of poly(butylene adipate)diol, 4,4'-diphenylmethane diisocyanate, and 2-hydroxyethyl acrylate, was used as a prepolymer. The prepolymer was semicrystalline and showed a melting point in the region of 50-60°C. The maximum polymerization rate of the prepolymer was obtained when the prepolymer film was irradiated in the temperature range of 25-40°C. EB polymerization below the melting point ( $T_m$ ) of the prepolymer produced semicrystalline polyurethane-acrylate gel films with a spherulitic texture. On the other hand, EB polymerization above the  $T_m$  destroyed the crystalline phase of the prepolymer to give transparent gel films. The gel film cured below the  $T_m$  had higher stress at yield, Young's modulus, and tensile strength than those cured above the  $T_m$ . Such temperature effects are attributed to whether or not the EB polymerization proceeds with retention of crystalline structure of the prepolymer. (Author abstract) 16 refs.

**083023 SYNTHESIS AND CHARACTERIZATION OF POLYISOBUTYLENE PROPELLANT BINDERS.** Substantial gains in rocket motor cost-effectiveness or performance can be achieved through improved propellant aging characteristics or better and more reproducible mechanical properties. The approach is achieving these goals is the development of a new binder based on ideal networks formed from polyisobutylene (PIB) prepolymers. PIB prepolymers evaluated in this study were synthesized using the 'inifer' process which allows close control of molecular weight distribution, functionality and types of end group. Hydroxy-terminated PIB's with molecular weights that varied from 1500 to 6000 and functionalities of 2 or 3 were synthesized. After a thorough characterization, gumstocks were prepared with isocyanate curatives of controlled functionality. The effect of  $M_c$  and plasticizer content on mechanical properties were determined in addition to the aging characteristics of the systems. Accelerated aging studies of the gumstocks were conducted. (Edited author abstract) 2 refs.

**083024 SOLUBLE POLY(BISMETHYLENE HYDROQUINONE): SYNTHESIS AND PROPERTIES.** Soluble poly(bismethylene hydroquinone) (PBHQ) of two different intrinsic viscosities and degrees of ring closure were synthesized. The polymers were chemically oxidized using bromine. The oxidation process was studied by comparison of the unoxidized and oxidized polymers using Fourier transform infrared,  $^{13}\text{C}$  solid-state CP/MAS NMR, elemental analysis, UV spectroscopy, and electron spin resonance. The oxidation-reduction processes of the polymers were studied using cyclic voltammetry. (Author abstract) 35 refs.

**083025 SYNTHESIS OF ALKENYLATED POLYAMINES AND STUDY OF THEIR PHYSICO-CHEMICAL PROPERTIES.** A series of oligoisobutylenes (OIB) with a different molecular weight and degree of unsaturation were used as the starting reagents for synthesis of the alkenylated polyamines. Oligoisobutylpolyamines (OIBPA) were synthesized by bromination of the starting OIB with subsequent substitution of the halogen by triethylenetetramine (TETA). As a result of the experiment performed, a series of alkenylated polyamines with a different concentration of nitrogen was obtained. The dispersing and anticorrosion properties were determined in a composite with M-11 base-stock oil for all of the compounds obtained. The results of these tests are reported and an analysis of the data showed that the dispersing capacity is a function of the concentration

of nitrogen in the compounds studied: the higher the concentration of nitrogen, the higher the dispersing capacity. 15 refs.

**083026 FUNCTIONAL POLYMERS; 47. SYNTHESIS OF VARIOUS DERIVATIVES OF  $\omega$ -ALKENOATES.** A number of derivatives of  $\omega$ -alkenoates was synthesized in preparation for the synthesis of functional polymers based on  $\alpha$ -olefins. For the preparation of most of the methyl esters, the regular esterification of  $\omega$ -alkenoic acids, specifically 10-undecenoic acid with methanol and sulfuric acid as the catalyst, was most effective. (Edited author abstract) 46 refs.

Purgett, Mark D. (Univ of Massachusetts, Amherst, MA, USA); Xie, Shishan; Bansleben, Donald A.; Vogl, Otto. *J Polym Sci Part A* v 26 n 3 Mar 1988 p 657-675.

**083027 FUNCTIONAL POLYMERS; 48. POLYMERIZATION OF  $\omega$ -ALKENOATE DERIVATIVES.** Esters of  $\omega$ -alkenoic acids have been homopolymerized with transition metal initiating systems. The key to the successful polymerization was the complexation of the monomer prior to its addition to the initiating system. Titanium trichloride, aluminum activated, was found to be best as the transition metal part of the initiator systems, with diethyl-, or better, diisobutylaluminum chloride as the reducing agents and *n*-hexane or toluene as the solvents. Best results for polymerizations were obtained with 2,6-dimethylphenyl esters of the functional  $\alpha$ -olefin monomers; however, other phenyl esters also polymerized well. (Edited author abstract) 48 refs.

**083028 SYNTHESIS OF POLYPHTHALOCYANINES BY AN OXIDOREDUCTION REACTION INITIATED BY THE BENZHYDROL FUNCTION GROUP. 1. MODEL STUDY.** A novel route for the thermal conversion of bis(phthalonitrile)monomers into metal-free phthalocyanine network polymers was investigated on the basis of a model study on the tetramerization reaction of 4-benzoylphthalonitrile and benzhydrol derivatives into metal-free phthalocyanine compounds. This procedure of conversion of phthalonitrile derivatives involved an oxidoreduction reaction initiated by the alcohol functional group of benzhydrol coreactant. The influence of molar ratio of phthalonitrile and benzhydrol functional groups, chemical environment of the benzhydrol reducing group has been studied by microcalorimetry and electronic spectroscopy. (Edited author abstract) 25 refs.

**083030 AMORPHOUS POLYARAMIDES WITH LOW GLASS TRANSITION TEMPERATURES.** Amorphous polyaramides with  $T_g$ s as low as 120°C have been prepared through the polycondensation of 3,3'-(sulfonylbis(1, 4-phenylenoxy))dibenzoic acid ( $Z=SO_2$ ) and

3,3'-(carbonylbis(1,4-phenylenoxy))dibenzoic acid ( $Z=CO$ ) with 3,3'-(1,3-phenylenedioxy)dianiline. The polymers were obtained by direct polycondensation of the aromatic diacids with the aromatic diamine and, alternatively, via the low-temperature polycondensation of the corresponding diacid chlorides with the aromatic diamine. 4 refs.

**083031 SYNTHESIS OF GRAFT POLYMERS BY COPOLYMERIZATION OF MACROMONOMER. III. PREPARATION AND COPOLYMERIZATION OF STYRENE-TERMINATED POLY(OXYETHYLENE) MACROMONOMER.** Styrene-terminated poly(oxyethylene) macromonomers (SOE) with narrow molecular weight distribution and quantitative styrene monofunctionality were synthesized. In homopolymerization of SOE, conversion of monomer to polymer was shown to be low in spite of high consumption of the vinyl groups of the SOE molecules. Free-radical copolymerization of the macromonomer with methyl methacrylate and styrene occurred smoothly, as opposed to homopolymerization. Cumulative copolymer composition and total conversion were determined from the conversions of macromonomer and comonomer (by weight changes) and by proton NMR of the copolymer. (Edited author abstract) 9 refs.

**083032 SYNTHESIS AND CHARACTERIZATION OF POLY(BENZIMIDAZOLYL)THIAANTHONES.** Novel polybenzimidazoles containing thiaanthone heterocyclic units were synthesized from 2,7-thiaanthonedicarboxylic acid-5,5'-dioxide and 2,8-thiaanthonedicarboxylic acid-5,5'-dioxide and two aromatic tetramine hydrochlorides by PPA solution polycondensation in 60-70% yield. Two model compounds, 2,7-bis(2-benzimidazolyl)thiaanthone-5,5'-dioxide and 2,8-bis(2-benzimidazolyl)thiaanthone-5,5'-dioxide, were prepared and characterized by spectral methods. The polybenzimidazoles have inherent viscosities in the range 1.13-1.50 dL/g and decomposition temperatures of 495-560°C. The effects of thiaanthone units on polymer properties are discussed. (Author abstract) 9 refs.

**083033 SULPHUR-CONTAINING POLYARYLENEQUINODIIMIDES.** Different synthetic approaches have been used for preparing some new polymers relating to sulphur-containing polyarylenequinodiimides. The latter have been obtained both from quinodiimidedichloride and aromatic dithiols and directly from 1,4-phenylenediamine and disulphenylchlorides. The mechanism of this process has been proposed on the basis of studying a model reaction of phenylsulphenylchloride with 1,4-phenylenediamine. Polyarylenequinodiimides have been obtained by selective oxidation of polyarylenesulphonamides with phenyliodooacetate. Their structure has been proved by IR, PMR, and <sup>13</sup>C-NMR spectroscopies. Electrophysical properties of synthesized polymers have been studied. (Author abstract) 24 refs.

**083034 BISMALEIMIDES CHAIN-EXTENDED BY IMIDIZED BENZOPHENONE TETRACARBOXYLIC DIANHYDRIDE AND THEIR POLYMERIZATION TO HIGH TEMPERATURE MATRIX RESINS.** Heat-resistant polymers were obtained by thermal polymerization of several bismaleimides or their substituted derivatives. The chain of the polymer precursors was extended by incorporation of imidized benzophenone tetracarboxylic dianhydride between the

maleimide rings in order to impart a degree of flexibility in the polymers. The bismaleimides and their corresponding tetraamic acids were characterized by infrared (IR) and proton nuclear magnetic resonance (<sup>1</sup>H-NMR) spectroscopy. The differential thermal analysis (DTA) thermograms of the monomers showed exotherms at 200-340°C attributed to the thermally induced polymerization reactions. (Edited author abstract) 7 refs.

**083037 SYNTHESIS AND PROPERTIES OF BISMALEIMIDE RESINS CONTAINING ETHER BONDS.** New bismaleimides containing ether bonds were prepared. The thermal properties of the bismaleimides were investigated by differential scanning calorimetry (DSC). The effects of structure of the bismaleimides and curing conditions on the thermal and mechanical properties of the cured resins such as initial decomposition temperature ( $T_d$ ), glass transition temperature ( $T_g$ ), and flexural strength were studied. The introduction of ether bonds to bismaleimide resins decreased the brittleness of the resins without reductions in their heat-resistant properties. (Author abstract) 9 refs.

**083038 ELECTROCHEMICAL SYNTHESIS AND OPTICAL ANALYSIS OF POLY[(2,2'-DIETHYNYL)-5,5'-DIYLVINYLENE].** The electrochemical synthesis of poly[(2,2'-dithienyl)-5,5'-diylvinylene tetrafluoroborate] (PDTE/BF<sub>4</sub>) has been accomplished and provides copper-black free-standing films with a room temperature four-probe conductivity as high as 15 (Ohm cm)<sup>-1</sup>. The conductivity and morphology of the films were found to be strongly dependent on synthetic conditions. The oxidized form of PDTE is not air stable, as evidenced by a rapid, three order of magnitude drop in the conductivity. Optoelectrochemical experiments demonstrate that bipolarons are the main charge-carrying species in conductive PDTE and allow their evolution to be followed as a function of oxidation. (Author abstract) 35 refs.

**083040 NEW FAMILIES OF MULTIBRANCHED MACROMOLECULES SYNTHESIZED.** Branching approach allows the construction of 'starburst dendrimers' and 'arborols' - new compounds that resemble polymers but exhibit precisely controlled size, shape and molecular weight. They have three distinguishing structural features: an initiator core, interior layers of repeating units radially attached to the core, and an outer surface of terminal functionality. Dendrimer synthesis is a stepwise process. The new macromolecules could be used right now to calibrate ultrafiltration membranes or to measure the submicron apertures of biomembranes.

**083042 CHEMICAL RELEASE CONTROL: SCHIFF BASES OF VINYLALDEHYDE AND FUNCTIONAL AMINES.** Schiff base (SB) monomers of vinylaldehyde with functional amines were prepared. Copolymers of SB monomers with N-vinyl-2-pyrrolidone soluble in aqueous solutions were obtained in most cases. However, p-aminobenzenesulfonamide monomer resulted in gel formation. Thus, the reaction of vinylaldehyde copolymer with the sulfonamide was used instead of the copolymerization. The hydrolytic behaviors of SB monomers and copolymers to liberate respective amines were structure dependent and, for most copolymers, the rates were lower than those of the corresponding monomers. (Author abstract) 3 refs.

**083043 INDENE-COUMARONE RESINS: SYNTHESIS AND APPLICATIONS.** Technical indene-coumarone resins are mixed polymers of indene, coumarone, styrene and their alkyl homologues. These resins are essentially low-molecular weight polymers varying in color from light yellow to dark brown and are usually hard and brittle. Indene-Coumarone (I-C) resins were introduced in the market in 1930 for the preparation of light-colored asphalt tiles. With improved techniques in the selection of raw material and assessment of its purity as well as in polymerization technique using newer catalysts, it has been possible to produce harder resins of better color and superior quality. Considerable R&D work is being done in several countries to improve the polymerization technique as well as to modify polymer properties by incorporating additives like acenaphthene, phenols and carbazole. The earlier cationic polymerization method is being gradually replaced by a novel radical

polymerization technique in the USSR. This paper reviews the R&D efforts on the synthesis of I-C resins during the last three decades and discusses the possibility of producing these resins from coal carbonization byproducts in India. 54 refs.

**083045 POLY(SCHIFF BASE) POLYMERS BASED ON SUBSTITUTED BISPHENYL.** The authors have been interested in the syntheses of novel poly(Schiff base) chelates because of their conductive and metal-coordinating properties. In principle, these polymers may incorporate catalytically-active redox functionalities which can be continually regenerated via electronic conduction through the polymer. Recent efforts of Elliot et al. to synthesize an electronically-conducting bipyridyl polychelate prompted the authors to investigate poly(Schiff bases) of the type reported in this paper. Some of the topics covered are cyclic voltammetry, physical, and spectral data. 13 refs.

**083047 PHOTORESPONSIVE VINYL POLYMER BEARING NORBORNADIENE AS A PENDANT GROUP.** The synthesis of a novel class of photoreactive polymers is reported. The norbornadiene unit in the polymer was found to be converted in the film state under nitrogen atmosphere to a quadricyclane unit reversibly with irradiation by UV light of two different wavelengths. Polymers bearing norbornadiene units having carboxylate and/or substituted amide groups at the 2- and 3-positions and having a vinyl group at the end of the 2-substituent were prepared by the polymerization of respective mono-

mers. Polymers bearing an amide substituent at the 2-position indicated a much higher photosensitivity in the film state as well as a larger red shift in the absorption spectrum than those bearing a carboxylate substituent. (Author abstract) 6 refs.

Kamogawa, Hiroyoshi (Yamanashi Univ, Kofu, Jpn); Yamada, Makoto. *Macromolecules* v 21 n 4 Apr 1988 p 918-923.

**083048 POLYMERIZATION AND BLOCK COPOLYMERIZATION INITIATED BY UNUSUALLY STABLE LIVING PROPAGATING SPECIES FORMED IN THE CATIONIC POLYMERIZATION OF SPIRO ORTHO CARBONATE.** The cationic polymerization of spiro ortho carbonate (SOC) forming a polyether-carbonate alternative copolymer is believed to proceed via trialkoxycarbonium ion (A) as a possible propagating species. Since this type of carbonium ion is well known to be quite stable as reported by Olah et al., this growing end should still remain living after the completion of the polymerization. We confirm the stability of the end species and disclose the preliminary results of it. It is shown that the polymerization of SOC is not the ideal living polymerization but has a few of the characteristics of living polymerization. Most interesting is the great stability of the growing end species. The authors believe that this study should provide a new polymerization process involving stable propagating species as well as an attractive entry to synthesize a wide variety of new block copolymers of considerably controlled molecular weights. 16 refs.

**083049 SYNTHESIS OF POLYPHENYLENE FROM A cis-DIHYDROCATECHEOL, A BIOLOGICALLY PRODUCED MONOMER.** Benzene is oxidized by oxygen utilizing the dioxygenase enzyme contained in the microorganism *Pseudomonas putida*. Genetic manipulation produced a variant that gave exclusively the initial oxidation product of benzene the cis-dihydrocatechol in practical quantities. Derivatives of the latter, in particular the methyl carbonate, can be obtained pure and very stable. They polymerize in the absence of solvent with radical initiators to give a polymer. The latter is soluble in solvents such as acetone and methylene chloride and readily forms coherent coatings and films. On heating methanol and  $\text{CO}_2$  are expelled and polyphenylene is formed as a coating or film. (Edited author abstract) 16 refs.

Ballard, D.G.H. (ICI PLC, Runcorn, Engl); Courtis, A.; Shirley, I.M.; Taylor, S.C. *Macromolecules* v 21 n 2 Feb 1988 p 294-304.

**083050 HIGH MOLECULAR WEIGHT POLYSILANES WITH PHENOL MOIETIES.** High molecular weight polysilanes substituted with pendant phenol moieties were prepared by sodium condensation of dichlorosilanes, whose phenolic OH groups were protected with trimethylsilyl ethers. However, monomers substituted with 4-hydroxyphenyl moieties did not give high polymers. The position of the OH in the benzene ring and the number of carbons between Ph and Si seem to determine whether or not the polymer has polysilane structure. The polymer (P(Me-m-1) ( $M_w$  110,000)) with 3-hydroxyphenyl moieties was prepared by gentle hydrolysis of PSI(Me-m-1) in methanol without serious molecular weight decrease. (Edited author abstract) 23 refs.

**083051 EFFECTS OF ORGANIC SIDE GROUP STRUCTURES ON THE PROPERTIES OF POLY(ORGANOPHOSPHAZENES).** Methods are reported for the synthesis of three new classes of poly(organophosphazenes) via the substitution reactions of poly(dichloro-

phosphazene). The first class consists of single-substituent polymers with aromatic rings separated from the main chain by methyleneoxy-spacer groups. The second and third classes comprise mixed-substituent polymers that contain aryloxy and aryl ester or aryl Schiff's base side groups. The variations in glass transition temperature with changes in side groups are discussed and are compared with the values for various alkoxy and alkoxy ether side group systems. (Edited author abstract) 33 refs.

Alcock, Harry R. (Pennsylvania State Univ, University Park, PA, USA); Connolly, Mark S.; Sisko, John T.; Al-Shali, Saman. *Macromolecules* v 21 n 2 Feb 1988 p 323-334.

**083052 ELECTROCHEMICAL SYNTHESIS AND PROPERTIES OF POLYCARBAZOLE FILMS IN PROTIC ACID MEDIA.** Conductive films are deposited onto Au by anodic oxidation of carbazole dissolved in aqueous alcoholic  $\text{HClO}_4$ . Cyclic voltammetry of film electrodes in aqueous  $\text{HClO}_4$  prepared in this way shows the occurrence of two main redox processes; an intermediate system becoming less important on cycling is ascribed to dimers or trimers. The polymer is remarkably stable when cycling involves only the first peak, while the second oxidation leads to degradation. An acid environment appears to be essential for film electrochemistry. ESR data confirm that protonation ensures conductivity of the material. On this basis, structure and conduction mechanisms similar to those of emeraldine are suggested. (Author abstract) 14 refs.

**083053 POLY([1.1.1]PROPELLANE)<sup>1</sup>. A NOVEL RIGID-ROD POLYMER OBTAINED BY RING-OPENING POLYMERIZATION BREAKING A CARBON-CARBON  $\sigma$ -BOND.** Treatment of the [1.1.1]propellane 1 with lithium organic initiators such as tert-butyllithium and phenyllithium leads to anionically induced ring-opening polymerization of 1. In the course of the polymerization only the central  $\sigma$ -bond in monomer 1 was opened, leading to an entirely new rigid-rod structure - the poly([1.1.1]propellane) 2, whose degree of polymerization was determined to be greater than 20. The rigidity of polymer 2 is due to constraints inherently associated with its multicyclic structure. The structure of the poly([1.1.1]propellane) 2 was proved by means of solid-state NMR spectroscopy and was further confirmed by an investigation of soluble, oligomeric material having analogous constitution. (Author abstract) 13 refs.

Schluter, Arnulf-Dieter (Max-Planck-Institut fuer Polymerforschung, Mainz, West Ger). *Macromolecules* v 21 n 5 May 1988 p 1208-1211.

**083054 SYNTHESIS OF A CHEMICALLY ORDERED LIQUID CRYSTAL POLYMER.** Links between chemical sequence structure in self-ordering polymers and their physics are still to be established. In order to address this problem we have proceeded to synthesize a sequentially ordered and regioregular terpolymer which exhibits liquid crystallinity. Neglecting end groups, this polymer is a constitutional isomer of a chemically random liquid crystal polymer reported previously. The synthesis of ordered-disordered chemical analogues has been difficult in the past either because of the absence of liquid crystallinity in highly regular chains or because of difficulties in developing regioregular polyesters. (Edited author abstract) 9 refs.

Moore, J.S. (Univ of Illinois at Urbana-Champaign, Urbana, IL, USA); Stupp, S.I. *Macromolecules* v 21 n 5 May 1988 p 1217-1221.

**083055 SYNTHESIS AND SOLID-STATE POLYMERIZATION OF A NEW DIACETYLENE: 1-(N-CARBAZOLYL)PENTA-1,3-DIYN-5-OL.** A new unsymmetrical diacetylene having a carbazoyl group directly bound to an acetylene moiety, i.e., 1-(N-carbazoyl)penta-1,3-diyn-5-ol, was synthesized. This diacetylene can be topochemically polymerized in the solid

state and the visible absorption edge of the polymer is expanded to nearly 800 nm, suggesting longer  $\pi$ -conjugation than the so-far-known polydiacetylenes. It is shown that the nonlinear optical susceptibility of poly-CPDO is larger than that of other polydiacetylenes. (Edited author abstract) 26 refs.

Matsuda, Hiro (Resarch Inst for Polymers & Textiles, Tsukuba, Jpn); Nakanishi, Hachiro; Hosomi, Takeshi; Kato, Masao. *Macromolecules* v 21 n 5 May 1988 p 1238-1240.

**083056 SYNTHESIS OF POLY(ADIPIC ANHYDRIDE) BY USE OF KETENE.** Polyadipic anhydrides were prepared (a) from the mixed anhydride of adipic acid and acetic acid, (b) from the mixed anhydride of adipic acid and ketene in tetrahydrofuran solution (0°C), (c) by melt polycondensation of adipic acid with ketene, and (d) from the seven-membered ring adipic anhydride. The polymers were characterized by means of NMR, IR, DSC, and GPC. The polymer with the highest melting temperature was obtained by melt polycondensation of adipic acid with ketene ( $T_{\text{peak}}$  76°C). The heat of fusion was approximately 40 J/g in all four methods. (Edited author abstract) 11 refs.

**083057 CONTROLLED ACTIVITY POLYMERS. IV. COPOLYMERS OF 2-(1-NAPHTHYLACETYL)ETHYL ACRYLATE WITH HYDROPHILIC COMONOMERS: SYNTHESIS AND CHARACTERIZATION.** 2-(1-Naphthylacetyl)ethyl acrylate (NAEA) was synthesized by esterification of 1-naphthylacetic acid (NAA) and 2-hydroxyethyl acrylate (HEA) and then polymerized to obtain the polymer-bound auxin NAA. The resulting polymer is potentially useful as a plant growth regulator through hydrolytic release of NAA. Copolymers of NAEA with hydrophilic comonomers were prepared by solution polymerization. The copolymer compositions were determined from elemental analysis, <sup>13</sup>C-NMR, and UV spectroscopy. (Edited author abstract) 25 refs.

**083058 SYNTHESIS OF POLY(ARYL ETHER-PHENYLQUINOXALINES).** As a means of preparing the quinoxaline-based analogue of the poly(ether-imides), we have investigated PPQ synthesis through a halo displacement approach. The results demonstrate that quinoxaline-based poly(aryl ethers) can be synthesized via a halo displacement polymerization, where the fused pyrazine ring is the activating group. The polymerization provides a general method for the preparation of aryl ether based PPQs, where the structure of the aryl ether moiety is readily controlled by varying the bisphenol used. 16 refs.

**083059 NOVEL SYNTHESIS OF POLY(1-t-BUTYLPYRROLIDIN-2-ONE-3, 4-DIYLETHYLENE) BY CYCLOPOLYMERIZATION OF N-t-BUTYL-N-ALLYLACRYLAMIDE.** This article describes an example of completely cyclized polymer with a unique ring size, i.e. 5-membered ring, which was prepared by the cyclopolymerization of N-t-butyl-N-allylacrylamide (t-BAA) as an unsymmetrical 1,6-diene. A mono-olefin, N-t-butyl-N-propylacrylamide (t-BPA), containing acryloyl moiety of t-BAA was shown also to polymerize well. As a model reaction, telomerization of t-BAA was carried out in the presence of benzenethiol as a telogen to give mainly 5-membered ring compound, 1-t-butyl-3-benzethioethyl-4-methylpyrrolidin-2-one, which suggested the structural unit of poly(t-BAA). 8 Refs.

**083060 SYNTHESIS OF FUNCTIONAL HYDRO-CARBON POLYMERS WITH WELL-DEFINED MOLECULAR STRUCTURES.** The preparation of well-defined functional polymers with narrow molecular weight distributions and functional groups homogeneously distributed along the polymer chains is described. The chemistry involves the hydroboration of polydienes. Since both thermodynamics and kinetics are favorable for this reaction, a completely homogeneous modification is obtained. The hydroborated polymers are valuable intermediates that can be converted to a variety of functional polymers. Polyalcohol is one of the examples that will be discussed in detail in this paper. To retain the narrow molecular weight distribution, several experimental methods, including vacuum techniques, low reaction temperatures, and boric acid removal, were employed during the reaction. The resulting functional polymers have molecular weight distributions of 1.07. (Edited author abstract) 27 refs.

**083061 POLY(ANHYDRIDES). 2. ONE STEP POLYMERIZATION USING PHOSGENE OR DIPHOSGENE AS COUPLING AGENTS.** Two approaches for one-step solution polymerization of poly (anhydrides) at ambient temperature were developed. In the first approach highly pure polymers (> 99.7 percent) were obtained by the use of sebacyl chloride, phosgene, or diphosgene as coupling agents and poly(4-vinylpyridine) or  $\text{K}_2\text{CO}_3$  as insoluble acid acceptors. The second approach for one-step synthesis of pure poly (anhydrides) was the use of an appropriate solvent where the polymer is exclusively soluble but the corresponding polymerization byproduct (e.g.,  $\text{Et}_3\text{N} \cdot \text{HCl}$ ) is insoluble. Under this condition polymerization of sebacic acid gave the best results in N,N-dimethylformamide and in toluene. (Edited author abstract) 19 Refs.

**083062 GLYCERYL POLYPHOSPHAZENES: SYNTHESIS, PROPERTIES, AND HYDROLYSIS.** Methylene-, isopropylidene-, and methoxymethylene-protected glyceryl units have been linked to cyclic and high polymeric phosphazenes. The structures and physical properties of these protected glyceryl-substituted phosphazenes were investigated by <sup>31</sup>P NMR, <sup>1</sup>H NMR, and IR spectroscopy and thermal analysis. Hydrolytic deprotection reactions in acidic media yielded the water-soluble cyclic trimeric and high polymeric glycerylphosphazenes. Cross-linking of the protected high polymers was accomplished by  $\gamma$  irradiation. The deprotected polymer cross-linked in the presence of adipoyl chloride or hexamethylene diisocyanate to yield systems that absorbed water to form hydrogels. Slow hydrolysis of poly(di-glycerophosphazene) occurred in neutral aqueous media at 37 °C to yield glycerol, phosphoric acid, and ammonia. (Author abstract). 36 Refs.

Alcock, Harry R. (Pennsylvania State Univ, University Park, PA, USA); Kwon, Sukky. *Macromolecules* v 21 n 7 Jul 1988 p 1980-1985.

**083063 PHENYLTHIAZYL POLYMERS WITH FLEXIBLE SPACERS: SYNTHESIS AND ELECTRICAL PROPERTIES.** A series of polymers with (phenylthio)phenyldithiazyl (PTPD series) and phenylenedithio-bis(phenyldithiazyl) (PDBPD series) segments have been synthesized by using a novel route involving the in situ chlorinolysis of a benzyl-protected precursor monomer. These polymers can be transformed from an insulating to a semiconducting state upon oxidation with bromine. The PTPD polymer made with a triethylene glycol spacer is soluble and fusible, while the ones with shorter spacers are

insoluble. The polymers attain conductivities in the range of  $10^{-3}$ – $10^{-5}$  ( $\Omega$  cm) $^{-1}$  on doping with bromine. (Author abstract). 16 Refs.

Chien, James C.W. (Univ of Massachusetts, Amherst, MA, USA); Ramakrishnan, S. *Macromolecules* v 21 n 7 Jul 1988 p 2007-2010.

**083064 [2,2]PARACYCLOPHANE END-CAPPED POLYQUINOLINE PREPOLYMERS: SYNTHESIS, PROCESSING, AND THERMAL PROPERTIES.** Flexible polyquinolines containing [2,2]paracyclophane end caps were prepared, using 4-acetyl[2,2]paracyclophane as the capping agent. Thermal analysis of the oligomers showed the [2,2]paracyclophane ring-opening exothermic maximum to be near 350 °C. The oligomers were melt-pressed at 350°C under a 5000-lb load for various times, giving high-quality films which exhibited good Young's moduli. Film quality and moduli were higher for the DP = 22 oligomer. TGA analysis showed the films to be stable to about 550°C in both air and argon. Oxidation aging at 320°C for 100 h gave moderate weight losses, relative to various quinoline oligomers end capped with biphenylene. (Edited author abstract). 13 Refs.

Upshaw, Thomas A. (Colorado State Univ, Fort Collins, CO, USA); Stille, J.K. *Macromolecules* v 21 n 7 Jul 1988 p 2010-2014.

**083065 ELECTROSYNTHESIS AND PROPERTIES OF RING-SUBSTITUTED POLYANILINES.** Electrochemical polymerization of ring-substituted anilines, with electron donor and acceptor substituents in the 2- and 3-positions, was investigated in 2.0 M sulfuric acid. Polymerization is mostly effective with sigma- and pi-donor substituents, the latter in the 2-position. Polymeric deposits were obtained from 2- and 3-methylaniline (toluidines), 2-methoxyaniline (anisidine) and 2-chloroaniline, and were characterized by cyclic voltammetry, elemental analysis, ir spectroscopy, uv-vis spectroelectrochemistry and electrical conductivity. Polytoluidine and polyanisidine are reversibly oxidized in two steps as polyaniline, whereas polychloroaniline is oxidized in a single one-electron process. Polymerization was found to be more effective on polyaniline-modified electrodes. (Author abstract). 17 Refs.

Cattarin, S. (CNR, Padua, Italy); Doubova, L.; Mengoli, G.; Zotti, G. *Electrochim Acta* v 33 n 8 Aug 1988 p 1077-1084.

**083066 SYNTHESIS AND CHARACTERIZATION OF LIQUID CRYSTALLINE COPOLYMETHACRYLATES, COPOLYACRYLATES, AND COPOLYSILOXANES CONTAINING 4-METHOXY-4'-HYDROXY- $\alpha$ -METHYLSTILBENE AND 4-HYDROXY-4'-METHOXY- $\alpha$ -METHYLSTILBENE CONSTITUTIONAL ISOMERS AS SIDE-GROUPS.** The synthesis of methacrylates and acrylates containing 4-methoxy-4'-hydroxy- $\alpha$ -methylstilbene and 4-hydroxy-4'-methoxy- $\alpha$ -methylstilbene constitutional isomers attached to the polymerizable group through flexible spacers containing 11, 8, 6, 3, and respectively 2 methylenic units is described. The radical copolymerization of a 1/2 or 2/1 mole ratio of the two constitutional isomeric monomers led to thermotropic side-chain liquid crystalline polymers in all cases. The synthesis of copolysiloxanes based on the same constitutional isomeric mesogens as side groups, and flexible spacers containing 11, 8, 6, 5, and respectively 3 methylenic units is also described. All polymers were characterized by differential scanning calorimetry and optical polarization microscopy. (Edited author abstract). 35 Refs.

**083067 SYNTHESIS AND CHARACTERIZATION OF POLY(METHYLENE TEREPHTHALATE).** Poly(methylene terephthalate) (IGT) has been synthesized via the reaction of cesium or potassium terephthalates with dibromomethane or bromochloromethane in N-methylpyrrolidone at temperatures of 80-125°C. The

polymerization was relatively slower with the latter substrate, though the potassium salt was found to be equally as efficient as its cesium counterpart with dibromomethane. The polymer is insoluble in all common polyester solvents, and its high molecular weight nature ( $D/P_n \geq 25$ ) was inferred from elemental analyses and its fiber forming capacity. (Edited author abstract). 31 Refs.

**083068 NEW TELECHELIC POLYMERS AND SEQUENTIAL COPOLYMERS BY POLYFUNCTIONAL INITIATOR-TRANSFER AGENTS (INIFERTS). LIII. LITHIATION OF 2,4,4-TRIMETHYL-1-PENTENE AND ISOPROPYLIDENE-CAPPED POLYISOBUTYLENES BY BUTYLLITHIUMS IN THE PRESENCE OF COMPLEXING AGENTS.** This report concerns model lithiation experiments of 2,4,4-trimethyl-1-pentene (TM1P) that guided us toward the subsequent quantitative lithiation of isopropylidene-telechelic PIBs. Thus, lithiation of TM1P with n-, s-, and t-butyllithium, in the presence of various complexing agents followed by silylation with Me<sub>3</sub>SiCl (for the purpose of quantitation) gave three products: 2(trimethylsilylmethyl)-4,4-dimethyl-1-pentene (TM1P-Si), 2(trimethylsilylmethyl)-4,4-dimethyl-2-pentene (TM2P-Si) and 1,1-di(trimethylsilylmethyl)-3,3-dimethyl-1-butene (TM2P-Si<sub>2</sub>). The relative product composition strongly depends on the BuLi/complexing agent ratio and temperature. (Edited author abstract). 29 Refs.

**083069 POLYMER-SUPPORTED BASES. IX. SYNTHESIS AND CATALYTIC ACTIVITY OF POLYMER-BOUND 4-(1-PYRROLIDINO)PYRIDINE MOIETIES.** Polystyrene-bound 4-(1-pyrrolidino)pyridine moieties were prepared by the reaction of chloromethylated polystyrene resins with pyrrolidinopyridine derivatives containing hydroxyl groups. The supported amines were effective catalysts for acylations of tert-alcohols or enols, acyl rearrangements, and diester synthesis from epoxides and anhydrides. Some of the low ring-substituted (8-15%) catalysts exhibited high activity comparable to that of 4-(N,N-dimethylamino)pyridine, though the activity was a little lower than that of 4-(1-pyrrolidino)pyridine. The recovered catalysts can be re-used, except for acyl rearrangements, without significant decrease in activity. (Author abstract). 34 Refs.

**083071 POLY(PHENYLENE SULFIDE): SYNTHESIS FROM 1,4-DIBROMOBENZENE AND SODIUM SULFIDE.** A new route to synthesize poly(p-phenylene sulfide) by nucleophilic substitution of 1,4-dibromobenzene with sodium sulfide in N-methylpyrrolidone is described. Kinetic evaluation shows the reaction to be of second order with two distinctive rate constant regimes. The first rate constant is higher and is operative until 50% conver-

sion, whereas in the second regime (between 50 and 92% conversion) the rate is slower. The kinetics of this route is compared under identical conditions with the conventional synthesis based on 1,4-dichloro benzene and sodium sulfide. (Author abstract). 9 Refs.

Rajan, C.R. (Natl Chemical Lab, Pune, India); Nadkarni, V.M.; Ponrathnam, S. *J Polym Sci Part A* v 26 n 9 Aug 20 1988 p 2581-2588.

**083072 ORGANOTIN POLYMERS. XII. AZEOTROPY IN BINARY AND TERNARY COPOLYMERIZATION REACTIONS OF DI(TRI-N-BUTYLITIN) ITACONATE WITH ACRYLIC ACID ESTERS, STYRENE, AND ACRYLONITRILE.** Binary and ternary copolymerizations of di(tri-n-butyltin) itaconate (TBTI) with methyl acrylate (MA), ethyl acrylate (EA), n-butyl acrylate (BA), styrene (ST), and acrylonitrile (AN) were carried out in solution at 70°C in the presence of a free-radical initiator. Experimental terpolymerization data agreed well with calculations based on the Alfrey-Goldfinger equation. The determination of unitary, binary, and ternary azeotropies of the various systems studied was easily handled by a computer. Ternary azeotropic compositions for TBTI-MA-AN and TBTI-EA-AN systems were 37:48:15 and 9:80:11 mol percent, respectively. Also, 'Pseudo-azeotropic' regions were identified where the deviation between feed and polymer compositions is very small. (Author abstract). 15 Refs.

**083073 FORMATION OF MIXED THERMOTROPIC LIQUID CRYSTALLINE SYSTEMS BASED ON AROMATIC POLYESTERS WITH MESOGENIC AND FLEXIBLE FRAGMENTS IN THE MAIN CHAIN.** The effects of polymolecularity and heterogeneity of the chemical structure of the flexible fragments on the conditions of formation and the order parameter of mixed liquid crystal systems are discussed, using aromatic polyesters with mesogenic and flexible fragments in the main chain as examples. It is shown that at close values of the temperature ranges over which liquid crystal order of the mixed components of different molecular weight exists, the order parameter of the mesogenic fragments of the mixture in the liquid crystal state is less than the corresponding values for homopolymers. In the case of a mixture of components with flexible fragment of different length and the same mesogenic fragments, the components of the system are completely incompatible in the liquid crystal state. (Author abstract). 16 Refs.

**083074 SYNTHESIS AND CHARACTERIZATION OF PHENYL SUBSTITUTED POLYPHENYLENE-VINYLENES.** A new polymerization process was successfully employed to synthesize defined structure, soluble, fusable, film forming, thermally stable and photoconductive poly-phenyl substituted phenylene-vinylene. The photoconductivity of these polymers, in term of spectral distribution and intensity of photocurrent, correlated with their structure. The thermal stability was high and increased as the H-value in polymer was decreased. The combination of photoconductivity with high temperature stability, however, is a new and interesting aspect of phenylated poly-phenylene vinylenes. 4 Refs.

**083075 SYNTHESIS AND CHARGE-TRANSPORT PROPERTIES OF POLYMERS DERIVED FROM THE OXIDATION OF 1-HYDRO-1'-(6-PYRROL-1-YL)-4, 4'-BIPYRIDINIUM BIS (HEXA-FLUOROPHOSPHATE) AND DEMONSTRATION OF A pH-SENSITIVE MICROELECTROCHEMICAL TRANSISTOR DERIVED FROM THE REDOX PROPERTIES OF A CONVENTIONAL REDOX CENTER.** This article describes the synthesis and electrochemical properties of redox polymers, having a polypyrrole backbone and viologen subunits, derived from oxidative electropolymerization of 1-methyl-1'-(6-pyrrol-1-yl)-hexyl)-4,4'-bipyridinium (P-V-Me<sup>2+</sup>) and 1-hydro-1'-(6-pyrrol-1-yl)hexyl)-4,4'-bipyridinium (P-V-H<sup>2+</sup>). Closely spaced Au microelectrode arrays modified with the polymers can be used to study aspects of the charge-transport behavior of the viologen redox system. Poly(P-V-Me<sup>2+</sup>) and poly(P-V-H<sup>2+</sup>) have been used to investigate the characteristics of microelectrochemical transistors based on a viologen redox center and a similar redox center, protonated monoquaternized bipyridinium, which is pH dependent. The device based on poly(P-V-H<sup>2+</sup>) shows a pH-dependent  $I_p$  at fixed  $V_G$ , as expected from the electrochemical behavior from reversible protonation of the terminal N of the bipyridinium group of poly (P-V-H<sup>2+</sup>). (Edited author abstract). 25 Refs.

**083076 QUARTZ MICROBALANCE STUDY OF THE ELECTROSYNTHESIS OF POLYPYRROLE.** An electrochemical quartz crystal microbalance has been used to study the anodic electropolymerization of pyrrole and concurrent deposition of polypyrrole onto gold in acetonitrile and propylene carbonate using tetraethylammonium tosylate, tetrabutylammonium tetrafluoroborate, and lithium perchlorate. Simultaneous dynamic measurements of charge and mass have been used to monitor the efficiency of the polymerization/deposition process as a function of film thickness and electrodeposition rate. This work demonstrates that the early stages of film formation are affected by the solubility of the oligomers formed and that the ultimate efficiency is electrolyte dependent. Additionally, it is shown that the polymerization process exhibits second-order reaction kinetics with respect to monomer concentration. (Author abstract). 40 Refs.

Baker, Charles K. (Univ of Texas at Arlington, Arlington, TX, USA); Reynolds, John R. *J Electroanal Chem Interfacial Electrochem* v 251 n 2 Sep 23 1988 p 307-322.

**083077 POLYMERIC PHthalOCYANINES AND THEIR PRECURSORS. 13. SYNTHESIS, STRUCTURE AND ELECTROCHEMICAL PROPERTIES OF THIN FILMS OF POLYMERIC PHthalOCYANINES FROM TETRACARBONITRILES.** Thin films (45-1200 nm thickness) of polymeric phthalocyanines were prepared by the reaction of copper films on various carriers with gaseous aromatic tetracarbonitriles. The films were characterized by IR, UV/VIS, and ESCA spectra. The electrical conductivity is in the order of  $10^{-2}$ - $10^{-5}$  S cm<sup>-1</sup>. The electrochemical activity of the films on graphite was studied in acid and alkaline electrolyte. The films exhibit rapid reduction and reoxidation. The pH dependence corresponds to that of the hydrogen electrode approximately. (Author abstract) 28 refs.

Wohrle, Dieter (Univ Bremen, Bremen, West Ger); Schmidt, Volker; Schumann, Bernd; Yamada, Akira; Shigehara, Kiyotaka. *Ber Bunsenges Phys Chem* v 91 n 9 Sep 1987, Discuss Meet: Phys and Chem, of Unconv Org Mater, Wiesbaden-Naurod, West Ger, Apr 29-May 1 1987 p 975-981.

**083078 HIGHLY CONDUCTING IODINE-DOPED POLY(COPPER-YLENE) FROM PHENYLACETYLENE.** Poly(phenylethynylcopper) (PPECu) was synthesized by reaction of the corresponding acetylenic compound with cuprous iodide. Infrared, Raman and ultraviolet spectroscopy showed that PPECu is a coordination polymer having substantial back coordination from the

filled metal d-orbitals to the antibonding orbitals of the acetylene groups. PPECu is a good insulator. On doping with iodine, the dc conductivity of PPECu is enhanced by about 13 orders of magnitude. The conductivity slightly decreases with increasing temperature. The thermopower is small and nearly temperature independent. Based on electron impact, IR, and uv spectroscopy it is concluded that charge-transfer complexes are formed between phenylethynylcopper and iodine. The conduction mechanism of iodine-doped PPECu can be understood in the framework of the theory that describes electrical conduction in quasi-one-dimensional mixed-valence stacked complexes. (Edited author abstract) 4 refs.

**083079 POLYMERIZED MICELLES - FACT OR FANCY?** Many micro particles have been examined as encapsulation and support materials for both physical and chemical applications. Particles of different sizes from nm downwards have presented a wide range of opportunities. Recently emphasis has been focussed on synthetic vesicles. This work deals with a large number of quaternary ammonium amphiphiles. The micellar character of the monomers has been demonstrated and polymerization attempted. Though the results show superficially facile polymerization in the micellar state and the formation of oligomers consistent with a topochemical process, in fact the reactions are much more complex than this. The results are discussed in terms of the known dynamics of micellization and polymerization processes and a narrow window within which a polymerized micelle might be achievable is defined. **083080 RESOLUTION OF ENANTIOMERS BY HPLC ON CHIRAL POLYMERS.** A useful chiral polymer was prepared by asymmetric anionic polymerization of triphenylmethyl methacrylate. The chirality of the optical active polymer arises only from the isotactic rigid helix polymer chain. The polymer was adsorbed to about 20 wt% on macroporous silica gel (10  $\mu$ m). The resulting chiral stationary phase gave an efficient HPLC (high performance liquid chromatography) column able to resolve more than 150 enantiomers including hydrocarbons, ethers, esters, ketones, amides, metal complexes etc. Methanol or aqueous methanol was found to be the best eluent, suggesting that hydrophobic interactions are important for chiral recognition. (Edited author abstract)

**083082 DESIGN OF SUBMICROSCOPIC POLY-ALDEHYDE MONOSPHERES FOR BIOLOGICAL APPLICATIONS.** Monodisperse polyaldehyde microspheres, e.g., polyglutaraldehyde and polyacrolein microspheres were formed by polymerization of the monomers in the presence of an appropriate surfactant which has both steric and electrostatic stabilizing effects. The conditions and the mechanism for obtaining monodisperse systems were studied. The microspheres were prepared via several mechanisms, in various sizes and with designated physical and chemical properties. The reaction of these microspheres through their aldehyde groups with ligands containing various functional groups, e.g., amine, thiol and carboxylate, is discussed. The effect of temperature and pH on these reactants is illustrated. The polyaldehyde microspheres with the desired properties were used for applications such as specific cell labeling and separation, cell culturing, affinity chromatography and specific hemoperfusion. (Author abstract)

## Synthetics

**083086 POLYMERIC PHOTOINITIATORS CONTAINING SIDE CHAIN BENZOPHENONE CHROMOPHORES: RELATIONSHIPS BETWEEN STRUCTURE AND ACTIVITY.** The synthesis of new benzophenone containing polymers and their behavior as initiators for the polymerization under UV irradiation of

acrylic monomers, is reported. Poly(4-vinylbenzophenone) [poly(VBP)] shows the same activity as that of poly(4-acryloxybenzophenone) [poly(ABP)] but much higher activity than the low molecular weight model compound, 4-isopropylbenzophenone (PPB). Even higher activity is observed for copolymers of VBP or ABP with (—)-methyl acrylate (MA) and 2-hydroxyethyl acrylate (HEA). The results are discussed in terms of intramolecular hydrogen abstraction by excited benzophenone moieties from the co-units having hydrogen donating groups and of conformational rigidity. Photophysical properties of the polymeric samples confirm that the intramolecular hydrogen abstraction is the main mechanism of activation of the polymeric systems. (Edited author abstract) 44 refs.

**083087 OVERLOADING AND DEGRADATION STUDY IN GPC USING LOW ANGLE LASER LIGHT SCATTERING DETECTOR (LALLS).** The unique macromolecular compression effect or delayed GPC elution of high M.W. material was observed using the GPC+LALLS technique for a polystyrene standard of M.W. 5.0 E5. Further overloading which resulted in nonlinear fractionation is also described. The degradation of a 4.2 E6 standard after elution was detected by LALLS with calculated M.W. of 1.0-1.1 E6 but not by GPC, as indicated by normal GPC retention time and the shape of the chromatogram. (Edited author abstract) 6 refs.

**083088 SIMULTANEOUS EPR ELECTROCHEMICAL MEASUREMENTS ON POLYFLUORENE IN AMBIENT TEMPERATURE IONIC LIQUIDS.** Simultaneous electron paramagnetic resonance (EPR) and electrochemical measurements have been carried out on polyfluorene prepared by monomer oxidation and utilized in an ambient temperature ionic liquid consisting of 1-methyl-3-ethylimidazolium chloride-aluminum chloride. A considerable EPR signal is observed in both the reduced and oxidized states; the EPR signal achieves a maximum value coincident with the peak current during a cyclic voltammogram. Assuming that the process is two one-electron steps, initially forming a radical cation, the difference between the two  $E^0$  values is estimated as less than 70 mV. (Author abstract) 16 refs.

**083089 PRECISION IN POLYMER TESTING: AN IMPORTANT WORLD-WIDE ISSUE.** This paper gives an overview of the action on precision assessment currently being conducted in ASTM Committee D11 and ISO/TC-45, both of these being devoted to Rubber and Rubber Product testing. Definitions for precision, i.e. repeatability and reproducibility, are given in addition to details on the organization of interlaboratory programs needed to acquire the basic precision data. A precision example using the Mooney viscosity test is presented as well as a discussion of the uses of precision parameters and the problems currently being encountered in this work. (Edited author abstract) 7 refs.

**083091 STUDIES OF THE FRICTION OF POLYMERIC MATERIALS.** The static and dynamic coefficients of friction of seven polymers in polymer-on-polymer and polymer-on-steel contact have been measured. It appears that the dynamic friction is independent of the sliding velocity and temperature, provided the temperatures attained are not sufficient to soften the polymer thermally; continued sliding, however, can modify the polymer surface and so affect the friction. The static friction coefficients were determined before and after the dynamic measurements and after the specimens had stood overnight. All the coefficients of friction obtained in these various ways were related functionally to one another and, presumably, for a given polymer, the values were influenced by adsorption or desorption from the polymer surface. The friction increased fairly regularly with the critical surface energy of the polymer. (Author abstract) 20 refs.

Vaziri, M. (Univ of Manchester, Manchester, Engl); Stott, F.H.; Spurr, R.T. *Wear* v 122 n 3 Mar 15 1988 p 313-337.

**083092 INVESTIGATION OF THE WEAR OF POLYMERIC MATERIALS.** A study has been made of the wear of the polymers, polytetrafluoroethylene, polypropylene, polyoxymethylene, high density polyethylene, poly(vinyl chloride), polyamide and poly(methyl methacrylate), during sliding against abrasive papers, polished steel and like polymer counter-surfaces. With the exception of poly(methyl methacrylate) and, to a lesser extent, polytetrafluoroethylene, there is a reasonable correlation between the wear rate of the polymer against abrasive paper and an expression involving the ploughing component of friction, the hardness, the tensile strength and the elongation to failure of the polymer as measured in tensile tests. Adhesive wear rates for like-on-like sliding are approximately proportional to the abrasive wear rates against SiC abrasive papers, although the absolute values are about  $10^5$  times smaller. (Edited author abstract) 12 refs.

**083093 FRACTURE MECHANICS OF POLYMERS. CRITICAL EVALUATION FOR LINEAR ELASTIC BEHAVIOUR AT HIGH SPEED TESTING.** Over the last few years considerable effort has been made to obtain reliable stress intensity factor and strain energy release rate ( $K_{IC}$  and  $G_{IC}$ ) data on polymeric materials. Experience has shown that a valuable method to minimize viscoelastic losses and plastic deformation is to work at high speed. However, some problems remain for this experimental method which have to be solved before standard methods can be defined. On the basis of measurements done with 3-point bending geometry on poly(vinylchloride) (PVC) and poly(propylene) (PP) at room temperature and over a range of notch depths, the work demonstrates that the linearity of experimental data both in the load ( $F$ ) and in the energy ( $U$ ) against  $(2BW^2/3LY)^{1/2}$  and  $(BW\phi)$  plot is not a critical test for linear elastic behaviour so that  $K_{IC}$  and  $G_{IC}$  values can be affected by large errors. Only the knowledge of the experimental curves which can be obtained by means of instrumented pendula in optimized test conditions allows a critical test to be applied for linear elastic behaviour based on comparison between experimental and predicted data for load, displacement and energy. These tests show that the linear elastic fracture mechanics, LEFM, criterion is satisfied for PVC but not for PP. This conclusion is further supported by the morphologies of the fracture surfaces. (Author abstract) 15 refs.

**083095 EFFECT OF THE NATURE OF THE POLYMERIC MATRIX ON THE EFFICIENCY OF BROMINE-CONTAINING FLAME RETARDANTS.** Processes occurring in the pre-flame zone of the condensed phase between  $Sb_2O_3$  and the bromine-containing antipyrines in compositions with polyolefins have been studied. The composition of the solid products of thermal decomposition and combustion of these compositions was investigated using X-ray, atomic emission and chemical methods of analysis. During the reaction of  $Sb_2O_3$  with hydrogen halide, halides and oxides of antimony are formed. It was shown that formation of antimony metal in the condensed phase had a negative effect on antipyrine efficiency. (Author abstract) 10 refs.

**083096 METHODS OF INVESTIGATION METHODS OF MEASURING THE ELASTICS MODULUS IN IMPACT TESTS ON POLYMERS.** It is shown that the results of determining the elastic modulus of polymethyl methacrylate in impact tests by means of the free methods currently available are completely in agreement provided allowance is made for weakening of the intermolecular bonds during deformation arising from their non-linearity (anharmonicity). Various methods have been proposed recently for measuring the elastic modulus of polymers, E under the conditions obtaining in impact tests. The values of E obtained by various methods differ in absolute value. Thus, the values of E for polymethyl methacrylate (PMMA) as determined previously are 2.16, 4.87, and 7.2 GPa respectively, for the same test conditions. The use of these methods thus requires interpretation and refinement, which is the object of this work. (Edited author abstract) 8 Refs.

## Theory

**083097 THEORY OF THE BEHAVIOUR OF FLEXIBLE POLYMERS IN LIMITED VOLUMES.** The proposed theory describes the equilibrium properties of flexible Gaussian chains in slot-like pores for any ratio of chain dimensions R, slot width D and arbitrary energies of adsorption of units on pore walls. It is shown that there are five characteristic modes of behavior covering the entire range of the R and D values and the adsorption energies. For each mode of behavior analytical expressions were derived for the free energy of a chain, the density profile for units inside a pore and the fraction of units located on pore walls. (Author abstract) 11 refs.

**083099 ON THE THEORY OF LINEAR DIATOMIC POLYMERS.** The model of linear diatomic polymers is considered. Both the ground state and the phonon spectrum of a discrete AB chain are investigated. Taking into account the electron-phonon coupling as well as the finite-band corrections, an expression for the sound velocity is derived. The continuum equations of motion in the finite-band scheme are constructed. The kink solution is analyzed when the effects of an order of  $O(1/L)$ , where  $L$  is a chain length, are included. It is shown that the low-lying electronic excitations of an AB chain with fixed end atoms are the kink pairs where each kink has an irrational charge and a spin  $\sigma=0$  (or  $\sigma=1/2$ ). Depending on the value of the parameter  $\alpha$  the odd-membered chain with a free boundary is obtained to contain either a soliton or an electron-hole pair in its ground state. At  $\alpha=0$  all results obtained are valid for the trans-polyacetylene model. (Edited author abstract) 17 Refs.

**083100 SOLITONS AND POLARONS IN POLYLYNE DISCRETE LATTICE AND BROKEN ELECTRON-HOLE SYMMETRY EFFECTS.** A SSH-like Hamiltonian proposed by M.J. Rice et al. for polylyne extended by second neighbor hoppings is investigated. The discrete system of electron eigenvalue equations together with self-consistency conditions for relative atomic displacements is numerically solved for a rich variety of soliton and polaron states. In particular, it is found that various degeneracies inherent for the model mentioned above are lifted due to terms which break the charge conjugation symmetry. Discrete lattice effects enhance the symmetry breaking. For polarexcitons and neutral solitons (antisolitons) an internal charge structure is found. (Author abstract) 18 Refs.

**083104 STUDY ON THE THERMOSTABILITY OF POLYETHERIMIDE.** Polyetherimide (PEI) was synthesized from Bisphenol A and 4,4'-bis(3-nitrophthalimido) diphenyl ether by the nitro-displacement reaction in a polar aprotic solvent, and its structure was identified. The thermal degradation kinetics of PEI was studied by thermogravimetric analysis under the protection of nitrogen, while the data were fitted with a double-variable regression. The estimated kinetic parameters were 5.33 th, 192 kJ/mol,  $1.45 \times 10^{12} \text{ min}^{-1}$  for the apparent order, activation energy and pre-exponential factor of reaction respectively. The good agreement with the results from H.L. Friedman method justified this mathematical approach to calculating the kinetic parameters for thermal decomposition. (Edited author abstract) In Chinese. 12 refs.

**083105 THERMALLY STIMULATED CURRENTS IN POLY(BIS(P-FLUOROPHENOXY)PHOSPHAZENE).** Thermally stimulated currents (TSC) were examined for poly(bis(p-fluorophenoxy)phosphazene) (PBFP) film. TSC showed peaks at the glass transition temperature ( $T_g = -4^\circ\text{C}$ ) and at  $T(1)$  ( $160^\circ\text{C} - 170^\circ\text{C}$ ), where  $\alpha$ -form crystal phase transformed to mesophase of  $\gamma$ -form structure. Another peak was found at  $T_{cc}$  between  $T_g$  and  $T(1)$ . Linear relationship between polarization field and peak current of  $T_{cc}$ -peak was found, which shows that  $T_{cc}$ -peak was caused by motion of dipolar groups in crystalline phase. When heating (up to  $200^\circ\text{C}$ ) and cooling (down to  $20^\circ\text{C}$ ) thermal process was repeated,  $T_{cc}$ -peak shifted to higher temperature region approaching  $T(1)$  and simultaneously, the peak current of  $T(1)$ -peak became smaller. Activation energy, time constant of dipolar relaxation and charge mobility were evaluated for  $T_{cc}$ -peak. From these results, it was concluded that  $\alpha$ -form and more ordered  $\beta$ -form crystalline phases coexisted in PBFP once heated above  $T(1)$  and the content of  $\beta$ -form phase increased by repeated thermally hysteresis. (Author abstract) 9 refs.

**083106 THERMAL BREAKDOWN OF POLYBIS-MALEIMIDAMINES.** The authors have attempted to perform a detailed study of the PBMA (Polybis-maleimidamines) thermal breakdown process, using dynamic and isothermal thermogravimetry on small samples (4-10 mg) of polymer prepared from purified monomers, and also using mass spectrometry and IR spectroscopy. It is found that in the initial stage of thermal and thermooxidative breakdown ( $300-350^\circ$ ) of polybismaleimidamines, regardless of their chemical structure, the predominant reaction is the reverse of the reaction of nucleophilic addition of active hydrogen of the primary amino group of the aromatic diamine to the double bond of the maleimide ring. The weakest bond proves to be the N-C bond between the amino group and the succinimide ring. The main product of thermal breakdown is the diamine. 12 refs.

Khabenko, A.V.; Titkova, Z.L.; Dolmatov, S.A. *J Appl Chem USSR* v 60 n 6 pt 2 Jun 1987 p 1281-1286.

**083107 NATURE OF THE THERMAL STABILITY OF POLYHETEROOARYLENES.** The dependence between structure and thermal stability of polyheteroarylenes has been examined. It has been shown that the thermal stability of polymers depends on the two basic factors - an energy factor, determined by the breaking energy of skeletal bonds in the polymer chain, and an entropy factor, which characterizes the probability of effecting the elementary acts of chemical reactions and is expressed via the mobility of the macromolecules. Symmetry of the monomeric units in a chain, regularity in the macromolecules, the absence of bulky substituents, and a high degree of crystallinity aid in reducing the molecular mobility of heterocycloaromatic polymers and in increasing their thermal stability. Analysis of the factors which aid in thermal stability has made it possible to arrive at the conclusion that the polymer glass transition point or melting point can serve as a criterion of the thermal stability of polyheteroarylenes. 21 refs.

Kalashnik, A.T. *Fibre Chem* v 19 n 4 Jul-Aug 1987 p 251-257.

**083108 VIBRATIONAL SPECTROSCOPIC STUDY OF THE THERMAL DEGRADATION OF POLYARYLENE METALLOSULPHIDES.** The authors have studied the processes of thermal degradation of polyarylene metallosulphides in vacuo and in presence of oxygen by IR spectroscopy in the region  $150-4000 \text{ cm}^{-1}$ . From analysis of the low-frequency vibratory spectra ( $290-400 \text{ cm}^{-1}$ ) it has been established that thermal degradation begins with rupture of the sulphur-metal bond. The differences in thermal degradation in vacuo and in presence of oxygen depending on the nature of the metal and the presence in the chain of a heteroatomic bridge are discussed. (Author abstract) 10 refs.

Shubina, Ye.S. (Nesmeyanov Inst of Elemento-Organic Compounds, USSR); Epshtein, L.M.; Kravtsov, D.N.; Shevlyakova, N.P.; Nedel'kin, V.I.; Gribkova, P.N.; Pavlova, S.-S.A.; Sergeev, V.A. *Polym Sci USSR* v 29 n 2 Feb 1987 p 244-252.

**083109 THERMAL DEGRADATION OF POLY(ARYL-ETHER-ETHER-KETONE) (PEEK): A DIFFERENTIAL SCANNING CALORIMETRY STUDY.** Differential scanning calorimetry (DSC) has been used to study the crystallization kinetics and thermal characteristics of poly(aryl-ether-ether-ketone) (PEEK) samples heated under a variety of conditions. Samples were heated in nitrogen and air at temperatures between  $380$  and  $420^\circ\text{C}$  for times up to 120 min. The results indicate that as the holding time and temperature of the melt increased, the amount of recrystallizable material decreased, especially when heated in air. Isothermal crystallization kinetics confirmed the presence of a two-stage crystal nucleation and growth process with Avrami exponents of the order of about 2.4 and 1.5 for the first and second processes, respectively. (Edited author abstract) 17 Refs.

Day, M. (Nat'l Research Council of Canada, Ottawa, Ont, Can); Suprunchuk, T.; Cooney, J.D.; Wiles, D.M. *J Appl Polym Sci* v 36 n 5 Aug 20 1988 p 1097-1106.

**083110 THERMAL DEGRADATION OF HIGH NITRILE BARRIER POLYMERS.** Effects of absorbed moisture on degradation behavior of high nitrile barrier polymers were monitored using thermogravimetric analysis techniques. Non-modified and 10 percent rubber modified samples were heated isothermally at nitrile processing temperatures ( $200$  to  $240^\circ\text{C}$ ) in air and nitrogen environments. Degradation was evaluated in terms of weight loss as a function of heating time and sample coloration. It was determined that complete removal of moisture, as well as high moisture concentration, contribute to increased degradation at the temperatures evalu-

ated. Moisture levels in the range of 0.15 to 0.5 percent were found to minimize degradation. (Edited author abstract). 13 Refs.

## Thermoanalysis

**083113 FEW CHARACTERIZATION STUDIES ON SOME POLY(METHYL ARYLOXYMETHACRYLATES).** High polydispersity values obtained for the molecular weights, as determined by light scattering, osmometry, and GPC, of polymers prepared by different methods from the monomers recently synthesized indicate the presence of large quantities of low molecular weight species besides the high molecular weight species. Intrinsic viscosity data were used to evaluate Mark-Houwink constants K and 'a' for this new series of monomers. DSC analyses show that the polymers have low T<sub>g</sub>. X-ray diffraction studies made on the fibers show a high percentage of crystallinity in poly(methyl a-phenoxy-methacrylate). (Author abstract) 15 refs.

**Thermodynamics** See Also POLYETHYLENES—Rheology; POLYVINYL ACETATE—Aging.

**083119 UTILIZATION OF THE CONCEPT OF QUASI SOLUTIONS IN THE THERMODYNAMICS OF POLYMER HOMOLOGUES.** It is proposed that an infinite sequence of linear polymer homologues be described as an open thermodynamic system whose equilibrium state is characterized by an additional param-

eter, i.e. by the length of macromolecules. Thus idea has led to the derivation of basic equations of the energy of a system: the repeat-units of chain molecules and the endgroups figure as independent components, like other substances present in the system. An analysis of the phase equilibria led to the derivation of an analogue of the known generalized differential van der Waals equation. (Author abstract) 5 refs.

Golubev, V.M. (Zhdanov State Univ, Leningrad, USSR); Rusakov, A.I. *Polym Sci USSR* v 28 n 7 Jul 1987 p 1734-1737.

**083120 ASPECTS OF THERMODYNAMICS OF POLYMER MIXTURES.** In this brief review article some aspects of the thermodynamics of polymer mixtures are discussed, mainly based on the author's research. The studies of poly(methyl methacrylate)/chlorinated polyethylene (CPE), poly(butyl acrylate)/CPE and CPE/CPE (different chlorine content) mixture verify the 'dissimilarity' and 'similarity' principles for predicting miscibility of polymer mixtures. The sign of heat of mixing of oligomeric analogues is not sufficient in predicting the miscibility. The Flory equation of state theory has been applied to simulate the phase boundaries of polymer mixtures. The empirical entropy parameter Q<sub>12</sub> plays an important role in the calculation, this reduces the usefulness of the theory. With energy parameter X<sub>12</sub> ≠ 0 and Q<sub>12</sub> ≠ 0 the spinodals so calculated are reasonable compared to experiments. A hole model was suggested for the statistics of polymer mixtures. The new hole theory combines the features of both the Flory equation of state theory and the Sanchez lattice fluid theory and can be reduced to them under some conditions. (Author abstract) 20 refs.

**083121 NEW PVT EQUATIONS FOR POLYMERIC LIQUIDS AND GLASSES.** New equations of state have been derived from our multiple hole energy model that describe the pressure-volume-temperature (PVT) behavior of amorphous polymers in both the equilibrium liquid and nonequilibrium glassy states. Good agreement between the theoretical and experimental results is achieved over a broad range of temperatures and pressures with a single set of molecular parameters. Significantly, all molecular parameters are independent of temperature and pressure and can be determined separately. (Edited author abstract) 17 refs.

**083122 IMPORTANCE OF ENTHALPIC INTERACTIONS IN POLYMERIC SYSTEMS.** Enthalpic interactions between blend components primarily determine the state of miscibility and many of the physical properties of the blend. Recent applications of these thermodynamic considerations are reviewed for a variety of systems, including binary and ternary blends of homopolymers, binary blends of copolymers with homopolymers, and polymer-solvent mixtures. Recent advances toward predicting polymer blend miscibility through use of a modified quasicheical thermodynamic model and heats of mixing data for liquids are also discussed. (Author abstract) 115 refs.

## Thermoelasticity

**083123 THEORY OF THERMOELASTIC PROPERTIES FOR POLYMER GLASSES.** We derive expressions for the extensional elastic moduli as functions of temperature and pressure by a generalization of the equation of state theory. Our previous efforts in this direction were confined to the low-temperature region, where the characteristic free volume function, defined by theory, is effectively frozen. We proceed now to higher

temperatures, where the temperature and pressure dependence of this function play a decisive role. The static Young's and shear modulus and the Poisson ratio are computed, based solely on equation of state information. This is illustrated by means of applications to poly(vinyl acetate) glasses at low and elevated pressures and for different formation histories. (Edited author abstract) 23 refs.

### Thickness Measurement

**083124 HYDRODYNAMIC THICKNESSES OF POLYETHYLENE OXIDES ADSORBED IN POROUS MEDIA UNDER POOR SOLVENT CONDITIONS.** The hydrodynamic thickness  $L_H$  of an adsorbed polyethylene oxide (PEO) layer on the wall of a porous filter was determined by measuring volume flow rates of aqueous 0.45 M  $K_2SO_4$  solution corresponding to a poor solvent for PEO through the pores as a function of molecular weight  $M_w$ .  $L_H$  increased with adsorption time and well attained its equilibrium value after 1 week for each sample. The time required to attain the equilibrium value became longer with increasing molecular weight. The plateau  $L_H$  values are comparable to the radii of gyration of free PEO chains in aqueous 0.45 M  $K_2SO_4$  solution and scale as  $M^{0.68}$ . The absolute value of the plateau  $L_H$  was larger than that in water (good solvent condition). The larger value of  $L_H$  is in qualitative agreement with calculated results. (Edited author abstract) 25 refs.

**083125 LIGHTGUIDING IN LANGMUIR-BLODGETT FILMS OF PREFORMED POLYMERS.** Preformed polymers, made from derivatives of vinyl-maleic anhydride copolymers, have been used to produce thick (300-400 layers; 0.5-0.6  $\mu$ m) Langmuir-Blodgett multilayers. The thermal stability of the films is shown to depend on the relative positions of the side-groups. Those materials which deposited well for large numbers of layers and possessed thermal stability were investigated for evidence of optical waveguiding using light at a wavelength of 633 nm. An attenuation of approximately 10 db  $cm^{-1}$  was observed in films having a thickness of about 0.5  $\mu$ m after suitable precautions were taken to exclude dust and bacteria. (Author abstract) 16 refs.

**083126 FORMATION OF  $Si(PH_2THALOCYANINATO)(OH)_2$  AND  $[Si(PH_2THALOCYANINATO)_2]_n$  FILMS AND THEIR OPTICAL AND ELECTRICAL PROPERTIES.** In this study we investigate the substrate temperature  $T_s$  dependence of the properties of films obtained by the evaporation of  $Si(Pc)(OH)_2$ . It is found that  $[Si(Pc)(OH)_2]_n$  films can be obtained when  $T_s > 240^\circ C$  and  $Si(Pc)(OH)_2$  films when  $T_s < 200^\circ C$ . Several interesting features are found in the absorption spectra and photoelectrical properties of the films obtained. 12 refs.

**083127 SURFACE RESTRUCTURING OF POLYMERS.** Time-dependent contact angle measurements are employed to follow the dynamics of surface modifications

of various polymeric surfaces of different hydrophilicities. The equilibration of a hydrophilic polymer in a strong polar environment (such as water) induces an increase in the polarity of the surface; the subsequent exposure of the restructured solid to a nonpolar environment decreases the polarity of the surface. The dynamics of these processes depends on the history of the specimen. Various phenomena, such as surface restructuring by the reorientation of the buried polar or nonpolar moieties, water penetration into the polymer, and the reorganization of water in the neighborhood of the surface, are suggested to be responsible for the time evolution of the dynamic contact angles. (Author abstract) 14 refs.

**083128 ENERGY STATES IN POLYVINYL-FORMAL THIN FILMS.** Electrons with 6 keV energy have been used to probe the energy of states in 100 Å thin films of polyvinyl formal. The electron energy-loss spectra at several angles show plasmon formation. The angular correlations of the scattered and ejected energy-loss electrons have been observed using the (e, 2e) technique with a transmission coplanar scattering geometry. Many states contribute to the (e, 2e) spectrum and with our overall electron energy resolution of 14.2 eV, states with binding energies of 11, 22, 32, 43, 53, 67, 80 and 93 eV have been seen but not identified. Angular correlations of the states at 22 and 43 eV were made but do not assist with identification of the states. Further measurements with a better electron energy resolution are required. (Author abstract) 28 refs.

**083129 EFFECT OF A SOLID SURFACE ON THE ELASTIC PROPERTIES OF THIN EPOXY COATINGS.** The study of the elasticity of epoxy coatings on supports with a different surface energy permitted obtaining some data on their mechanical behavior in consideration of the adhesive interaction with the surface of the solid and qualitatively examining them with the current concepts of interphase events. Regulation of the elasticity of boundary layers of an epoxy polymer during its curing on a solid surface, for example, in coatings, adhesive compounds, and composite materials, could be attained by adding small amounts of SF to the composite. 18 refs.

**083131 SINGLE-ION CONDUCTION IN POLY[(OLIGO(OXYETHYLENE) METHACRYLATE)-co-(ALKALI-METAL METHACRYLATES)].** Thin films of poly[oligo(oxyethylene) methacrylate]-co-(alkali-metal methacrylates) were prepared from methanol solutions of oligo(oxyethylene) methacrylate and alkali-metal methacrylates by casting and polymerization on a Teflon plate under nitrogen. The ionic conductivity of the films depends on the electrolyte content, the dissociation energy of the alkali-metal methacrylate, and the degree of motion of polymer segments surrounding the ions in the polymer matrix. The ionic conductivity of the polymeric Li and K salts is  $10^{-6}$  S/cm at  $80^\circ C$ . The transient ionic current after reversing the dc bias polarity shows one sharp peak corresponding to cation migration, indicating that the polymer is a cationic single-ion conductor. (Edited author abstract) 34 refs.

**083133 CHARACTERIZATION OF POLYAMIC ACID/POLYIMIDE FILMS IN THE NANOMETRIC THICKNESS RANGE FROM SPIN-DEPOSITED POLYAMIC ACID.** A dilute polyamic acid solution was spin-deposited onto gold substrates and XPS analyses were performed after deposition. Evidence of the presence of organic films on the top surface of the substrates was found. A chemical characterization allowed us to identify these organic films as being polyamic acid after a  $125^\circ C$  curing and polyimide after a  $240^\circ C$  curing. From angle-dependent data we have shown that the good substrates were coated quasi-uniformly by ultra-thin films. This conclusion was confirmed by an Auger analysis. The computed thicknesses were found in a range of 1.3 to 2.9 nm depending on the sample preparation conditions. Adsorption was supposed to occur just after the deposition. Some possible mechanisms of the interfacial interaction between the polyamic acid and the surface were proposed. A thermally-activated chain cleavage was supposed to occur at the interface or near the interface. (Author abstract) 40 refs.

**083134 PARAMETER MEASUREMENT OF POLYMER THIN FILM WITH QUASI-WAVEGUIDE METHOD.** A new experiment for measuring the parameters of polystyrene and polyethersulphone films using quasi-waveguide method is reported. The films were deposited on the substrates with the shape of prism. Leaky mode m-lines of the films were measured. The index and the thickness of the films were determined by using leaky mode equation. The birefringence of the film was obtained with the aid of different polarized laser beam. The measurement errors of the index and thickness are about  $\pm 1 \times 10^{-3}$ , and  $\pm 0.01 \mu$ m respectively. (Author abstract) 5 refs. In Chinese.

**083135 LANGMUIR-BLODGETT FILMS OF ACETALIZED POLY(VINYL ALCOHOL)S.** Monolayers and multilayers of amphiphilic polymers consisting of acetalized poly(vinyl alcohol) (PVA) having various linear aliphatic side chains were investigated and their electrons beam (EB) exposure characteristics were measured. It was found that monolayers of acetalized PVA having long alkyl side chains were stable on water and could be deposited onto both hydrophobic and hydrophilic substrates with a deposition ratio of 1.0. The resulting multilayers and hydrophilic substrates with a deposition ratio of 1.0. The resulting multilayers were Y type. The wettability of the multilayers changed according as there was an odd or an even number of layers. The thickness per layer increased with the length of the alkyl side chain. These results suggested that Langmuir-Blodgett (LB) films of acetalized PVA having long alkyl side

chains were rather well-ordered with the side chains directed normal to the main chains. (Edited author abstract). 15 refs.

**083136 WORKSHOP ON THE MOLECULAR ENGINEERING OF ULTRATHIN POLYMERIC FILMS.** The proceedings contains 22 papers. Some of the specific topics discussed are: experimental considerations in insoluble spread monolayers; pre-Langmuir-Blodgett monolayers; physical properties of ordered ultrathin organic films; lipid-based tubule microstructures; phase-controlled surface reactions; and thin organic films of proteins. All papers are separately indexed and abstracted. Technical and professional papers from this conference are indexed and abstracted with the conference code no. 10531 in the Ei Engineering Meetings (TM) database produced by Engineering Information, Inc.

**083137 CHEMISTRY OF POLYMER MOLECULES FOR ULTRATHIN FILMS.** Progress in polymeric resist materials for microlithography has partly allowed the advent of very-large-scale integrated circuits. Use of conveniently oriented ultrathin films of liquid crystal polymers for non-linear optics seems very attractive since the films can be produced much faster than crystals can and at greatly reduced cost. They can be applied over very large areas relative to the crystal size and on various substrates. This paper is a review of the main families of polymers for making resists useful in microlithography and of polymers exhibiting liquid crystal properties. (Edited author abstract) 136 refs.

**083138 ORIENTED ULTRATHIN MEMBRANES FROM MONOMERIC AND POLYMERIC AMPHIPHILES: MONOLAYERS, LIPOSOMES AND MULTILAYERS.** Oriented polymeric membranes were originally prepared by polymerization or polycondensation of preoriented monomers. The introduction of hydrophilic spacer groups into the polymeric amphiphiles allowed the formation of highly ordered systems (monolayers, liposomes and multilayers) from prepolymerized amphiphiles. In monolayer experiments the high degree of order of these membranes can be demonstrated by their surface pressure vs. area diagrams. Polymeric liposomes can be prepared by ultrasonication of prepolymerized lipids. In addition, the combination of the order and mobility of these polymeric amphiphiles with hydrophilic spacer groups allowed the formation of Langmuir-Blodgett multilayers with a high layer correlation. (Edited author abstract) 32 refs.

**083139 LANGMUIR-BLODGETT FILMS MADE FROM PREFORMED POLYMERS.** A brief general review of work in this field is given. A particular family of copolymers derived from maleic anhydride is described and the way in which these copolymers behave at the air-water interface and as Langmuir-Blodgett multi-layers is discussed with particular reference to the influence of the nature of the side-chains on isotherms and structure. The application of these materials to the formation of low loss optical waveguides, electron beam resists and photo-diodes is reviewed. (Author abstract) 28 refs.

**083140 MOLECULAR ENGINEERING IN JAPAN - A PROSPECT OF RESEARCH ON LANGMUIR-BLODGETT FILMS.** The present status of research on Langmuir Blodgett (LB) films in Japan is outlined in relation to molecular engineering. Stress is laid on the fundamentals of LB films: synthesis of novel films, advances in preparation techniques, and characterization of molecular domains. The advances in characterization are exemplified by the introduction of Penning ionization electron spectroscopy, the utilization of synchrotron radiation and analyses using the electron spin resonance technique applied to dye LB films and conducting LB films. The prospects for molecular engineering in the near future are briefly discussed. The significance of the LB technique as a tool for fabricating test structures is pointed out together with the increasing importance of theoretical guidelines. (Edited author abstract) 91 refs.

**083141 PHASE-CONTROLLED SURFACE REACTIONS.** Discrete interfacially controlled condensation and addition reactions, including polymerization, are described in the case of conducting polymer film growth on salt crystals, as well as monolayer reactions on a water surface. It has been shown that the interface controls and limits the extent of reaction so as to minimize structural disruption of the film material. In virtually every case, the resulting polymer has a unique chemistry, structure, defect level or purity which cannot be obtained by any other method. (Author abstract) 18 refs.

Lando, Jerome B. (Case Western Reserve Univ, Cleveland, OH, USA); Rickert, Scott E. *Thin Solid Films* v 152 n 1-2 Sep 14 1987, Workshop on the Mol Eng of Ultrathin Polym, Davis, CA, USA, Feb 18-20 1987 p 327-333.

**083142 FUTURE APPLICATIONS OF ORDERED POLYMERIC THIN FILMS.** Polymeric ultrathin film systems need to be developed in the context of applications where their unique combinations of properties promise revolutionary improvements in performance or cost effectiveness. The applications examined include electron beam resists for microlithography and nanolithography, insulating films in semiconductor devices, non-linear optical elements and coatings for communications and computing, as well as highly permselective membranes in biotechnology. In this paper, we will review some of the most appealing suggestions and evaluate their current status. Improvements in film characterization and deposition based on Langmuir-Blodgett techniques are also suggested. (Author abstract) 56 refs.

**083145 THIN LAYERS OF POLY(F-FLUOROALUMINIUM-PHTHALOCYANINE).** Among the poly(metal-phthalocyanines), (AlPcF)<sub>n</sub> exhibits the property of being easily sublimated and therefore deposited as thin layers on various substrates, which makes its characterization easier. Owing to its ionization potential equal to 4.55 eV, it can be doped by oxidants such as O<sub>2</sub>, I<sub>2</sub>, NO<sub>2</sub> and Cl<sub>2</sub>. We present here the variations of dc conductivity of (AlPcF)<sub>n</sub> layers doped with NO<sub>2</sub> or O<sub>2</sub> as a function of time, temperature, gas concentration and layer thickness: the results are interpreted through Langmuir's theory on gas adsorption and desorption. ## Ultrafiltration

**083146 METHODS OF INVESTIGATION THE INFLUENCE OF PRESSURE ON THE ULTRAFILTRATION OF POLYVINYLPIRROLIDONE.** The practicability of dialysis has been investigated for polydisperse polymers subjected to membrane ultrafiltration with programming of pressure, taking polyvinylpyrrolidone as an example. It was found that ultrafiltration is an effective method of dialysis in the case of samples for which  $M_w/M_n > 3$ . The dialysis of narrowly disperse samples ( $M_w/M_n < 2$ ) necessitates very careful selection of the conditions of experiments. The extremal character of the effect of pressure on dialyzing properties of the membranes has been detected. (Author abstract) 27 refs.

## Vibrations

**083147 NEW METHOD FOR REFINING THE VIBRATIONAL FREQUENCIES AND MODES ON CALCULATION OF THE VIBRATIONAL SPECTRA OF POLYMERS.** Based on the generalized Jacobi rotation method, we propose an effective algorithm for the transition to the first-order approximation of the theory of infrared spectra of polymers. We show that the proposed method is, on the one hand, equivalent to the second-order Rayleigh-Schrodinger perturbation theory for nondegenerate zeroth-order-approximation frequencies, and on the other hand, makes it possible to avoid the difficulties associated with the existence of degeneracies or quasidegeneracies. 3 refs.

**083148 EFFECTS OF CHAIN LENGTH DISTRIBUTION ON VISCOELASTIC PROPERTIES OF ENTANGLED LINEAR POLYMERS: BLENDING LAWS FOR BINARY BLENDS.** The reptation idea of de Gennes and the tube model theory of Doi and Edwards are extended to explain the terminal viscoelastic properties of binary blends in the highly entangled state of two linear monodisperse polymers with different molecular weights  $M_1$  and  $M_2$ . A modified tube model is proposed that considers the significance of the constraint release by local tube renewal in accounting for the relaxation process of the higher molecular weight chain. Its relaxation by both reptation and the constraint release is remodeled as the disengagement by pure reptation of an equivalent primitive chain. Theoretical predictions of the zero-shear viscosity and steady-state shear compliance are shown to be in good agreement with literature data on undiluted polystyrenes and polybutadienes over a wide range of the blend composition and  $M_2/M_1$  ratio. (Edited author abstract) 21 refs.

**083149 RELAXATIONAL INTERACTIONS AND VISCOELASTICITY OF POLYMER MELTS: PART II. RHEOLOGICAL PROPERTIES IN SHEAR AND ELONGATIONAL FLOWS.** The rheological equation of state derived in Part I on the basis of relaxation equations of chain dynamics is analyzed for the steady and transient shear and uniaxial elongational flows of monodisperse polymers. The effect of superslow relaxation processes associated with basic macromolecular motions that occur on a characteristic scale essentially greater than the so-called distance between entanglements was investigated in these flows. It is shown that the relaxation times in the region of linear and nonlinear viscoelasticity are self-consistent. Theoretical predictions are in good agreement with the experimental data for melts of nearly monodisperse flexible polymers. (Author abstract) 14 refs.

Volkov, V.S. (USSR Acad of Sciences, Moscow, USSR); Vinogradov, G.V. *J Non Newtonian Fluid Mech* v 25 n 3 Sep 1987 p 261-275.

**083150 VISCOELASTIC PROPERTIES OF (CELLULOSE OLIGO-OXYMETHYLENE ETHER) ACYLATES WITH BULKY SIDE CHAIN.** A series of (cellulose oligo-oxyethylene ether) acylates (COAs) are characterized by the presence of the micro-Brownian motion of the side chain ( $\beta$  process) which appears separately from that of the main chain ( $\alpha$  process). To clarify the effect of the acyl group on these processes, we investigated the dynamic mechanical properties of newly prepared COAs with acyl side chain, bulky in chemical structure (iso-butyrate, pivalate, and benzoate) in relation to those for COAs with linear acyl side chain (acetate, butyrate, and valerate). By substituting bulky acyl isomer for linear acyl group in COAs, we observed that the temperature region of both the  $\alpha$  and  $\beta$  processes moved to higher temperature. Furthermore, with an increase in molecular size of bulky acyl group, the  $\beta$  region shifts were much larger than the  $\alpha$  region, indicating that the mobility of the side chain became comparable to that of the main chain. Finally, when such a large bulky group, for example, benzoate was introduced, the micro-Brownian motion of the side chain prior to that of the main chain ceased. (Edited author abstract) 10 refs.

**083151 VISCOELASTIC BEHAVIOR OF AMORPHOUS POLYMERS NEAR THE GLASS TEMPERATURE.** Lack of thermorheological simplicity and possible effects of the molecular weight distribution in the softening dispersion of linear amorphous polymers are demonstrated with viscoelastic data on polymethylacrylate PMA and polyvinylacetate PVAc. Superposition of the short time portion of the softening transitions of the retardation spectra of PMA, PVAc, polystyrene, and amorphous polypropylene APP indicates that the local

molecular mobility is a constant at  $T_g$  within experimental uncertainty. The general features of the retardation spectra of linear amorphous polymers are discussed. (Author abstract) 36 refs.

**083152 COMPARISON OF GRAPHO-ANALYTICAL AND COMPUTER METHODS OF CALCULATING THE RELAXATIONAL SPECTRA OF POLYMERS.** In the linear theory of viscoelasticity various characteristics can be obtained from the Boltzmann-Volterra equation. There is another approach to describing viscoelastic behavior, consisting essentially in expressing all the viscoelastic functions in terms of one only, i.e. the spectral density of distribution of the relaxational time. Of all the possible approaches to describing viscoelastic behavior, the spectral description allows the most natural physical treatment. Relaxation spectrograms can be obtained from various experimental data, dynamic or static. Mostly data from stress relaxation experiments are used. Relaxational spectrograms obtained by both methods are presented. It can be seen from these data that there is an extremely close correlation between the computer and 'manual' spectrograms in the position and number of the spectral lines. 10 refs.

**083153 OVERVIEW OF THE VISCOUS AND VISCOELASTIC BEHAVIOR OF IONOMERS IN BULK AND SOLUTION.** The subject of the viscous and viscoelastic behavior of ionomer systems is addressed from a general point of view. The authors consider the glassy state followed with a more complete discussion of the rubbery and viscous flow (melt) states. The viscous and viscoelastic response of ionomer systems when in solution will then be discussed. We have also attempted to compare the so-called 'random copolymer' ionomers to the telechelic systems. Emphasis is given to single component materials in contrast to blends or filled systems. 129 refs.

**083154 NONCOOPERATIVE RELAXATIONS.** Dynamic mechanical studies have revealed a large class of internal motions having activation entropies close to zero which appear to involve well-defined structural units acting in a noncooperative manner. Examples include rotations of methyl groups, certain side-group motions, and local-mode relaxations which are restricted to short polymethylene sequences. Other cases, including grain boundary relaxations in metals, are associated with crystalline phases. (Author abstract) 24 refs.

**083155 CHARACTERISTIC NUMBERS OF POLYMERS IN DILUTE SOLUTION: A UNIVERSAL DESCRIPTION OF THE CROSS-OVER EFFECTS.** The viscosimetric behavior of eleven polymer-solvent systems is analyzed in order to determine the characteristic numbers in the beginning and in the end of the cross-over region. We show that in the beginning and in the end of the cross-over region the characteristic molecular weight or the characteristic number of monomers is different for different polymers and the second is related to the stiffness of the chain. In the contrary, the characteristic number of statistical segments in the beginning and in the end of the cross-over region are about the same for all the polymers, and this result confirms the validity of

a universal description of polymer solutions. (Edited author abstract) 21 refs.

**083156 ON THE TEMPERATURE-COMPOSITION SUPERPOSITION OF VISCOSITY IN POLYBLEND MELTS BASED ON THE SHEAR RATES.** Using the Vinogradov-Malkin coordinates it was found that temperature and concentration reductions (based on shear rates) of viscosity are obtainable for polyblend melts. If the components of a polyblend are similar as to their mode of flow, invariance is observed over the entire range of composition. Where there is a marked difference in the degrees of viscosity anomaly, invariance is observed for the dispersion medium whose melt is characterized by a larger viscosity anomaly and by higher elasticity. It appears from the experimental results that, despite changes occurring in the structure of the melt for a mixture of incompatible polymers during flow, steady conditions of flow appear in a capillary. (Author abstract) 20 refs.

**083158 ANOMALOUS TEMPERATURE DEPENDENCE OF VISCOSITY OF THERMOTROPIC POLYESTERS.** This paper is concerned with the temperature dependence of viscosity of liquid crystalline polymers. Certain compositions were observed to exhibit a positive temperature coefficient of viscosity (viscosity increasing with shear rate) over the entire shear rate range. Other compositions showed flow curves which intersected at critical shear rates. This behavior is explained by a variation in chain stiffness with composition (high hydroxybenzoic acid content resulting in stiffer chains) which results in a biphasic melt. The unusual rheological behavior is a manifestation of the competition between isotropic and anisotropic phases, which is influenced by composition, temperature, and shear. 13 refs.

**083159 STABILITY OF THE INTERFACE BETWEEN TWO DYNAMIC PHASES IN CAPILLARY FLOW OF LINEAR POLYMER MELTS.** Results of previous work on a theoretical explanation of the 'spurt effect' in polymer melt flow are extended. A modified Doi-Edwards liquid is shown to support axisymmetric traveling waves on an interface between high and low shear-rate phases in capillary flow. The stability of these perturbations is found to be governed by normal stress effects and may be related to certain types of melt fracture. Observed effects of varying the capillary length are explained qualitatively. (Author abstract) 10 refs.

**083160 VISCOMETRIC ESTIMATION OF UNPERTURBED CHAIN DIMENSIONS OF POLYMERS.** A new expression is proposed to determine the unperturbed dimensions of coil-like polymers viscometrically by use of the P.J. Flory and O. Kratky expression. The unperturbed dimensions so estimated are compared

with the results obtained by using different expressions available in the literature. The results are comparable even for stiff chain polymers. The data obtained under theta conditions also fit this expression very well. The effect of molecular weight, its distribution, and that of the solvent has also been studied. (Edited author abstract) 27 refs.

**083161 TRANSPORT COEFFICIENTS OF HELICAL WORMLIKE CHAINS. 4. INTRINSIC VISCOSITY OF THE TOUCHED-BEAD MODEL.** The intrinsic viscosity of the helical wormlike touched-bead model without excluded volume is evaluated by taking into account the effect of the finite volume of the bead. An empirical interpolation formula for it is presented. This formula is useful for an analysis of experimental data for flexible chains, if the data for low molecular weights are included. Some salient aspects of the behavior of the intrinsic viscosity over a wide range of molecular weight (or contour length) are discussed on the basis of the numerical results. In particular, it is found that the slope of the double-logarithmic plot of the intrinsic viscosity against the molecular weight becomes smaller than  $\frac{1}{2}$  as the helical nature becomes strong. (Edited author abstract) 25 refs.

**083162 COMPENSATION EFFECTS IN VISCOSITY-TEMPERATURE DEPENDENCE OF POLYMER MELTS.** The thermal dependence of the parameters of the Carreau A model of viscosity has been investigated for 13 polymeric resins. It was shown that the zero-shear viscosity and the time constant obey an Arrhenius-type law and that, for these parameters, compensation effects are exhibited. The shear-thinning index was found to be fairly independent of temperature. An important consequence of a compensation effect is that only one determination of a parameter at a given temperature gives the complete temperature-dependence of this parameter. (Author abstract) 18 refs.

**083163 SYNTHESIS AND PROPERTIES OF ARAMIDS AND POLYARYLATES HAVING PERFLUORO-SUBSTITUENTS ON THE BENZENE RING.** A new series of 16 aramids and 16 polyarylates having perfluoro-substituents on the benzene ring was prepared by a low temperature solution or an interfacial polycondensation. The effects of fluorine substituents on the structure and properties of polymers were examined. Fluorinated aramids exhibited higher crystallinity, while fluorinated polyarylates showed lower crystallinity. The melting point ( $T_m$ ) of aramids decreased with fluorine substitution, whereas  $T_m$  of polyarylates from fluorinated aromatic diols was higher than that of those from unfluorinated ones. The temperature of 10% weight loss and the residue at 900°C decreased with fluorine substitution except for the aramids from fluorinated diamines. (Edited author abstract). 12 Refs.

**083164 RECYCLING OF POLYMER WASTE: PART 1 - PHOTO-OXIDIZED POLYPROPYLENE.** In order to recycle photo-oxidized polypropylene, blends of this polymer waste with virgin polypropylene have been

prepared with different compositions. Both rheological and mechanical properties depend on composition. Rheological properties indicate some interactions between the two polymers at low shear rates. On the other hand, at high shear rates there is evidence of incompatibility. The nominal tensile strength is almost independent of the composition, while the other mechanical properties are similar to those of the degraded material up to a virgin PP content of about 75%, after which they quickly reach the values for the virgin polypropylene. These features are correlated with the large spherulite size of these blends. (Author abstract) 14 refs.

**083165 WEAR OF POLYMER COMPOSITE MATERIALS IN CORROSIVE-ABRASIVE MEDIA.** We examine the friction and wear of modified polyamide-6 and ED-20 epoxy resin in assemblies operating under the action of the aggressive and abrasive media used in agricultural production. As a result of these studies it is found that the corrosive-abrasive medium consisting of mineral fertilizers has the greatest influence on the wear of the polymer composite materials. The nature of the wear of the materials is determined by the nature and content of the disperse and fibrous fillers and by the composition of the corrosive-abrasive medium. It is established that the introduction of modifying additives reduces the influence of the aggressive media on the magnitude of the wear of the polymer materials. (Author abstract) 11 refs.

**083168 LARGE-ANGLE X-RAY SCATTERING STUDY OF TWO AMORPHOUS INORGANIC POLYMERS, Ru(SPH)<sub>2</sub> AND Mo(SPH)<sub>2</sub>.** We present a structural model for the amorphous polymers Mo(SPH)<sub>2</sub> and Ru(SPH)<sub>2</sub> obtained from LAXS experiments and relate this model to some observed physical properties. The best description of both polymers is obtained on the basis of alternating long and short metal-metal distances leading to a distortion of the octahedral geometry around the metal atoms. Using an undistorted model with equal M-S and M-M distances, it was not possible to obtain a correct broadness of the first peak, which represents the superposition of the first three coordination spheres around the metal: two sets of each three M-S bonds and

one M-M interaction. 18 refs.

**083169 STRUCTURE OF THE CRYSTALLINE COMPLEX BETWEEN POLY-( $\gamma$ -METHYL L-GLUTAMATE) AND CHLOROFORM.** The crystal structure of the complex between poly( $\gamma$ -methyl L-glutamate) (PMLG) and chloroform was studied by X-ray diffraction method. The PMLG main chain takes the right-handed  $\alpha$ -helical conformation, which is identical with that of the dry form. The unit cell of the complex is hexagonal with lattice dimensions  $a = 12.75$  Angstrom and  $c$  (fiber axis) = 26.9 Angstrom, and contains eighteen amino-acid residues and about three molecules of chloroform. The complex assumes a statistically disordered structure, where up and down helices are distributed randomly among the lattice sites, and molecules of chloroform locate favorably between antiparallel helices. The side-chain conformation is rather contracted. (Author abstract) 18 refs.

**083175 CORRELATION OF CHEMICAL STRUCTURE AND ELECTRICAL CONDUCTIVITY IN POLYPYRROLE FILMS BY X-RAY PHOTOELECTRON SPECTROSCOPY.** X-ray photoelectron spectroscopy was used to track chemical structure changes in conducting polypyrrole films which were electrochemically grown at various current densities. The film structures were correlated to changes in the film electrical conductivities. High resolution spectra of the C 1s, N 1s and O 1s regions were recorded. Concentrations of the charge compensating counter-ions used in the growth of the film were also monitored and correlated to electrical performance. Results indicated that the films grown at low current densities contained hydroxide anions and deprotonated nitrogen species, while films grown at high current densities contained no hydroxide ions or deprotonated nitrogens and exhibited higher charge removal from the pyrrole ring. At medium current densities, the amount of incorporated dopant anion was maximized. (Author abstract) 27 refs.

**083176  $^{13}\text{C}$  NMR METHOD OF INVESTIGATION IN THE STEREOCHEMICAL STRUCTURE OF METHYL METHACRYLATE BY RADIATION-INDUCED POLYMERIZATION.** This paper reports a study of a polymer sequence, and the striking changes with stereochemical configuration in polymethyl methac-

rylate (PMMA) by radiation-induced polymerization. The polymer structure was investigated by means of  $^{13}\text{C}$  NMR spectroscopy. The spectrum reveals seven separate resonance lines, which can be assigned to the ten possible pentads. Comparison of the observed and calculated intensities of the assigned resonances indicated that the Bernoulli statistics describe the radiation-induced polymerization mechanism of the PMMA sample under study. The experimental results show the radiation induced dose and the probabilities of isotactic, syndiotactic and heterotactic triads are a function of  $P_m$ , respectively. The preference of the propagation or degradation for the syndiotactic in PMMA can be found due to the activation enthalpy and dependence of radiation dose. The authors have estimated the N-ads distinction equation, and by using this distinction equation satisfactory results have been obtained. (Edited author abstract) 9 refs.

**083177 ASSIGNED COTACTIC PARAMETERS IN THE RADICAL COPOLYMERIZATION OF METHYL METHACRYLATE WITH VARIOUS METHACRYLATES.** Copolymers of totally deuterated methyl methacrylate with a small amount of various methacrylates were radically prepared in toluene and, if necessary, converted into the copolymer of MMA- $d_8$  with MMA. The assigned coisotactic parameters,  $\rho_{12}$  and  $\rho_{21}$ , were determined from their  $^1\text{H}$  NMR spectra. The values for the copolymerizations with triarylmethyl methacrylates ( $M_2$ ) such as triphenylmethyl, diphenyl-2-pyridylmethyl or phenyl-2-pyridyl-0-tolylmethyl methacrylates, were unequivocally different from each other. The results indicated that the addition of  $M_2$  to MMA radical end favored syndiotactic placement while the addition of MMA to  $M_2$  end occurred preferentially in isotactic way. The cause of this peculiar stereoregulation in radical polymerization was discussed in detail. (Author abstract) 27 refs.

**083178 ANALYSIS OF THE DISTRIBUTION OF MOLECULAR MOTION WITH RESPECT TO RELAXATION TIMES IN POLYMERS ON THE BASIS OF THERMOSTIMULATION OF DEPOLARIZATION.** A method is proposed for the transformation of thermostimulated depolarization curves into distributions, with respect to relaxation times, of molecular motion in polymers. The width and form of the distribution for  $\alpha$ - and  $\beta$ -relaxation processes in PMMA are analyzed. It is shown that the method proposed for treating TSD curves can be applied successfully to obtaining distribution functions with respect to relaxation times for molecular motion in polymers. (Edited author abstract) 14 refs.

Mansimov, S.A. (USSR Acad of Sciences, USSR); Kerimov, M.K.; Gezalov, Kh.B.; Kovarskii, A.L. *Polym Sci USSR* v 28 n 9 1986 p 2221-2226.

**083179 PREPARATION OF MICRON-SIZE POLYMER PARTICLES IN NONPOLAR MEDIA.** The dispersion polymerization of methyl methacrylate has been investigated using mixtures of carbon tetrachloride and 2,2,4-trimethylpentane as the dispersion medium and polyisobutylene as the steric stabilizer. It was found that as the concentration of carbon tetrachloride in the dispersion medium increased, the particle size increased with monodisperse particles of up to 13  $\mu\text{m}$  in diameter being produced. However, the molecular weight of the resulting polymer particles and polymerization kinetics decreased with increasing carbon tetrachloride concentration. It is suggested that the locus of the particle polymerization changes as the solvency of the dispersion medium for the resulting polymer is varied with a concomitant change in the size of the final particle. (Author abstract) 9 refs.

**Ablation** See Also POLYSTYRENES—Ablation.

**083181 FEMTOSECOND UV EXCIMER LASER ABLATION.** Experiments on the ablation of polymethylmethacrylate (PMMA) with 300 fs uv excimer laser pulses at 248 nm are reported for the first time. With these ultrashort pulses, ablation can be done at fluences up to five times lower than the threshold fluence for 16 ns ablation of PMMA, and the surface morphology is improved, also for several other materials. A model for ablation is proposed, assuming a non-constant absorption coefficient  $\alpha_{\text{eff}}$  depending on the degree of incubation of the irradiated material and the intensity of the incoming excimer laser pulse. The agreement between our model and our experimental observations is excellent for 16 ns excimer laser pulses, also predicting perfectly the shape of a pulse transmitted through a thin PMMA sample under high fluence irradiation. Qualitative agreement for 300 fs excimer laser pulses is obtained so far. (Author abstract) 16 refs.

**083182 ULTRAVIOLET LASER ABLATION AND ETCHING OF POLYMETHYL METHACRYLATE SENSITIZED WITH AN ORGANIC DOPANT.** Although polymethyl methacrylate (PMMA) is essentially transparent to light to 308 or 351 nm, it can be made sensitive to photoablation and etching by excimer laser pulses (20 ns half-width) of those wavelengths by the introduction of an organic dopant. The dopant (trade name= Tinuvin) is actually a quencher of the first electronic excited state of PMMA and is therefore used commercially to stabilize the polymer against photodegradation. Laser etching of Tinuvin-doped PMMA can be shown to be a photochemical process in which the Tinuvin decomposes by the absorption of two or more photons and causes the ablation of the surrounding polymer. (Author abstract) 11 refs.

**Adhesion**

**083183 KINETICS OF ADHESION DEVELOPMENT AT PMMA-SAN INTERFACES.** The kinetics of adhesion development at interfaces between poly(methyl methacrylate) (PMMA) and styrene/acrylonitrile (SAN) copolymers of varying AN levels have been studied at 130°C by measuring the tensile fracture strength of a butt joint configuration. For miscible pairs, SANs containing about 9.5 to 33% AN, the principal mechanism of adhesion development involves interdiffusion of PMMA and SAN chains with the joint strength growing in proportion to  $\tau^{1/4}$  (where  $\tau$ = time the joint is at 130°C) as predicted by theory. The interdiffusion rate is greatest near 14.7% AN, where the interaction with PMMA is maximum as demonstrated by recent studies of phase behaviour for PMMA-SAN blends. This optimum rate of

adhesion development is consistent with a stronger thermodynamic driving force for diffusion. (Edited author abstract) 41 refs.

## Adsorption

**083184 KINETICS OF POLYMER ADSORPTION MEASURED IN SITU AT THE SOLID-LIQUID INTERFACE: UTILITY OF THE INFRARED TOTAL INTERNAL REFLECTION METHOD.** The method of infrared spectroscopy in attenuated total reflection (IR-ATR) has been used to study kinetics of polymethylmethacrylate (PMMA) adsorption from dilute carbon tetrachloride solution onto a germanium prism at 27.0°C. By using a combination of deuterated and protio PMMA, it was possible to monitor the initial buildup of the adsorbed layer of one polymer species, followed by the time-dependent displacement of this species when the ambient polymer solution was changed. Data are presented for the displacement of adsorbed deuterated polymer of molar mass 57,000 g by protio polymer of molar mass 400,000 g, and for the displacement of adsorbed protio polymer of molar mass 64,000 g by deuterated polymer of molar mass 57,000 g. (Edited author abstract) 13 refs.

## Aging

**083185 EFFECT OF SORBED PENETRANTS ON THE AGING OF PREVIOUSLY DILATED GLASSY POLYMER POWDERS. PART III: THE EFFECT OF EXPOSURE TO LOWER ALCOHOLS ON ENTHALPY RELAXATIONS IN POLY(METHYL METHACRYLATE).** Enthalpy relaxations in glassy poly(methylmethacrylate) have been studied through the endothermic, sub- $T_g$ , aging peak observed in differential scanning calorimetry (DSC) thermograms. Powder samples were swollen by exposure to high activity methanol vapor and then aged in vacuum and in the presence of low activities of methanol, ethanol, and n-propanol at 308 K. The position and size of the DSC aging peak, which developed during aging, were monitored as a function of aging time. The aging peaks which developed for the alcohol-aged samples were smaller than those observed for similar samples aged in vacuum. These results suggest that the presence of dissolved penetrant in the samples retarded or arrested the relaxations which were observed in otherwise identical experiments performed in vacuo. (Edited author abstract) 30 refs.

**Blending** See Also FLUORINE CONTAINING POLYMERS—Crystallization; POLYCARBONATES—Blending; POLYMERS—Blending; POLYVINYL CHLORIDE—Blending.

**083187 LOW FREQUENCY DIELECTRIC RELAXATION STUDY IN PMMA/PS BLENDS.** The dielectric behaviour of solution-grown films of poly (methyl methacrylate) (PMMA)-polystyrene (PS) blends has been studied as a function of frequency and temperature. The obtained results show that the  $\beta$ -process observed in the PMMA/PS system is associated with the PMMA fraction in the blend. From the dielectric results we found that the local conformational states of the PMMA chain are perturbed by blending with a PS content higher than 9-13%, as a results of the incompatibility of this system. Balda, R. (Univ del Pais Vasco, Bilbao, Spain); Perez Jubindo, M.A.; de la Fuente, M.R.; Katime, I. *Mater Chem Phys* v 18 n 4 Dec 1987 p 359-373.

**083188 COMPATIBILITY AND LCST BEHAVIOR IN POLY(VINYLDENE FLUORIDE-CO-HEXAFLUOROACETONE)/POLY(METHYL METHACRYLATE) BLENDS.** Compatibility in poly(vinylidene fluoride-co-hexafluoroacetone) [P(VDF-HFA)]/poly(methyl methacrylate) (PMMA) blends was investigated experimentally. Glass transition temperature and refractive index of blends depend on the volume fraction. Lower critical solution temperature (LCST) type phase diagrams were obtained from transmittance-temperature measurements. Transmittance changes of the critical concentration blends were one step decreasing by spinodal decomposition; the changes for other blends were two step decreasing, by binodal and spinodal decompositions. LCST's were 245°C and 233°C when the molecular weight of PMMA was  $4 \times 10^4$  and  $12 \times 10^4$ , respectively. The LCST was about 330°C in PVDF/PMMA system, but it was found that copolymerization of HFA with VDF caused the LCST to shift to lower temperature. (Author abstract) 24 refs. In Japanese.

**083189 NMR STUDY ON THE COMPATIBILITY OF ACR / PVC BLENDS.** A 300MHz solid NMR study on the compatibility of ACR(poly(methyl methacrylate-co-methacrylate), in the ratio of 1:1)-PVC (poly(vinyl chloride)) blends is reported. Spin-lattice ( $T_1$ ) and spin-spin ( $T_2$ ) relaxation time of ACR, PVC and their blends are recorded in the temperature range from 215K to 355K. Experimental results indicate that ACR and PVC are compatible with each other and that the domain size is smaller than 25 nm, but that heterogeneities of molecular dimensions still exist. Some problems of mechanism of compatibility and data analysis are also discussed. (Edited author abstract). 8 Refs.

## Copolymerization

**083191 QUANTUM-CHEMICAL CALCULATIONS OF THE REACTION OF ISOCYANATES WITH COMPOUNDS, CONTAINING A POLARIZED C=C BOND.** The reaction of reagents with  $=\text{N}=\text{C}=\text{O}$  and  $>\text{C}=\text{C}<$  polarized bonds was examined on the methyl isocyanate-methyl methacrylate model system. Calculations were carried out by the semiempirical CNDO/2 method with optimization of geometrical parameters of molecules. Reasons for the impossibility of occurrence of the copolymerization process between methyl isocyanate and methyl methacrylate in the absence of active centers were shown on the basis of results of calculation of their stable conformers. The electronic structure of compounds of electron-donor nature (nitrogen-containing organic bases) was examined, and their catalytic activity in the copolymerization reaction of methyl isocyanate and methyl methacrylate was discussed. (Author abstract) 16 refs.

**Crack Propagation** See Also MATERIALS TESTING—Fatigue.

**083192 APPLICATION OF THE CRACK LAYER THEORY OF FATIGUE CRACK PROPAGATION IN PMMA.** The crack layer theory has been well established as a good description of the energy dependence of fatigue crack propagation in thermoplastics associated with multiple crazes or large deformation preceding the crack tip. Since PMMA usually displays crack propagation preceded by a single craze, the applicability of the theory in such extreme cases needs to be tested. Fatigue crack propagation data obtained in a previous interferometric investigation in PMMA have been utilized here. Two different approaches are attempted for estimation of the energy dissipated in craze formation and growth. (Edited author abstract) 25 refs.

**083193 CRACK PROPAGATION UNDER MODE II LOADING: AN EFFECTIVE STRESS INTENSITY FACTOR METHOD.** The prediction of crack propagation in brittle materials under mixed mode and particularly mode II loading requires the knowledge of the direction of crack propagation and the load that will initiate such propagation. In this paper, the maximum tensile tangential stress criterion is used to define an effective stress intensity factor. This method is applied to the Richard mode II specimen made of PMMA and a good agreement is obtained between the predicted and experimentally measured failure loads. The method presents the advantage that crack propagation can be predicted even in mixed mode by using only one material parameter. (Edited author abstract) 15 refs.

**083194 FRACTURE OF RADIALLY EDGE-CRACKED DISCS.** The brittle fracture of thin radially edge-cracked disks has been studied in three loading situations: edge opening, pin loading and diametral compression. Theoretical equations for these configurations are given and compared critically with experimental test on polymethyl-methacrylate samples. The edge-opening geometry was the best test overall, though all three systems were advantages when compared with other common toughness tests because of their exact theory, simple sample preparation, facile machining, easy pre-cracking, straight-forward loading and low propagation forces. (Author abstract) 17 refs.

Kendall, K. (ICI, Runcorn, England); Gregory, R.D. *J Mater Sci* v 22 n 12 Dec 1987 p 4514-4517.

**083195 DEFORMATION AND STRESS ANALYSIS OF THE CRAZE AT THE FATIGUE CRACK TIP IN POLYMETHYLMETHACRYLATE.** Deformation of the craze during fatigue cycling was measured continuously at the fatigue crack tip in polymethylmethacrylate by an optical interference method. Based on the line-zone craze model proposed previously, the measured craze contour was analyzed. With various heights machined from the model material PMMA. The dynamic stress intensity factors decrease at the beginning of the crack propagation phase, remain almost unchanged in the next stage, and then increase in all specimens. After this period the behavior of the stress intensity factors varies with the specimen geometry. The values of the stress intensity factors at three characteristic points in the stress intensity factor-crack extension curve are discussed with relation to the crack arrest. **083197 EFFECTS OF INITIAL MOLECULAR WEIGHT ON THERMAL DEGRADATION OF POLY(METHYL METHACRYLATE): PART 1 - MODEL 1.** The relationship between changes in degree of polymerization and conversion was obtained experimentally for three anionically polymerized PMMA samples with different initial degrees of polymerization (315, 1250 and 5690). Kinetic constants for random scission initiation and average zip length were determined by combined use of the experimental data and a theoretical model (Model 1) based on the same depropagation rate via  $\beta$  scission from both primary and tertiary radicals generated from random scission of backbone C-C bonds. Although the theoretically calculated activation energies for global reaction based on weight loss rates agree reasonably well with the experimentally determined activation energies, the theoretical estimates show inconsistency in the predicted value of average zip length and also do not agree well with the experimentally determined weight loss rates with temperature under dynamic heating conditions. It is suspected that the assumption of the equal reactivity of the primary and tertiary radicals is incorrect. (Author abstract) 21 refs.

**083199 O<sub>2</sub> PLASMA ETCH RATE REDUCTION ON SYNCHROTRON RADIATION EXPOSED PMMA FILM.** The etch rate of PMMA film in O<sub>2</sub> plasma is found to be reduced by synchrotron radiation (SR) exposure. This phenomenon is accompanied by a reduction in film thickness. IR and XPS analyses reveal that this thickness reduction is caused by scission and removal of the ester side chain. Etch rates of the SR-exposed film decreases to about 1/3 of the unexposed film. This characteristic makes dry-development possible. (Author abstract) 1 ref.

**Fiber Reinforcement**

**083200 MECHANICAL PROPERTIES OF GLASS-CARBON PMMA HYBRID COMPOSITES AT VARIOUS TEMPERATURES.** The fatigue of carbon fiber reinforced poly(methyl methacrylate) (CF/PMMA) has been investigated and it was decided to extend this study the mechanical properties at various temperatures of hybrid composites, containing both carbon and glass fiber. In this work carbon and glass fibers up to a total fiber content of 70% by volume were used to reinforce a PMMA matrix. The tensile and flexural properties of carbon/glass PMMA composites were examined at various temperatures amongst the transition temperatures. Even with 70% reinforcement the temperature of the  $\beta$ -transition appears to be the maximum at which engineering properties are retained. 4 refs.

**083202 FRACTURE SURFACE ENERGY MEASUREMENTS OF PMMA: A NEW EXPERIMENTAL APPROACH.** The paper describes the results of experiments on notched and cracked polymethyl methacrylate (PMMA) beams which have been subjected to tensile and impact loading. The dynamic load was applied to the edge of the beam by a projectile (steel sphere) fired from an air gun. The amplitude of the stress pulse has been carefully chosen so as to create a crack propagation that could be recorded step by step. Special attention has been paid to measuring the fracture surface energy by the method of caustics using the second step of the propagat-

ing crack. A marked difference has been found in the fracture surface energy calculated by the method of caustics using the first or the second step of propagation. The influence of the notch width on the fracture surface energy has also been studied in connection with cracked specimens, where the cracks have been induced by fatigue. Finally, a comparison of the results of the present work with the corresponding experimental data of previous investigations has been made. (Author abstract) 35 refs.

**Impurities**

**083204 EFFECT OF RADIATION AND IMPURITIES ON MICROSCOPIC DEFORMATION PROCESS IN PMMA.** Small-angle X-ray scattering experiments were conducted under various tensile stress levels for poly(methyl methacrylate) with different amounts of impurities and microscopic defects. Compared with a highly purified sample of optical fiber grade, the commercially available samples containing many impurities showed that the generation of submicrocracks starts at much lower stress levels. Furthermore, it was revealed that the number of size and such submicrocracks becomes larger in samples irradiated by  $\gamma$ -rays, which produce internal microscopic defects. These results suggest that such impurities and microscopic defects existing in the virgin samples tend to become nuclei for the submicrocracks upon the application of a tensile stress, causing a significant influence on the microscopic deformation process in amorphous polymers. **Molecular Weight**

**083206 SOME EXPERIMENTAL OBSERVATIONS ON NEARLY MONODISPERSE POLY-**

**METHYL METHACRYLATE AS AN ELECTRON RESIST.** Samples of nearly monodisperse polymethyl methacrylate, PMMA, of molecular weights ranging from 30,000-500,000 have been investigated. The sensitivity to electrons was found to improve with the use of low molecular weight PMMA which is attributed to its high solvent-polymer interaction parameter. The chemical nature of the solvent present in the film pre-baked below the glass transition temperature ( $T_g$ ) was found to have an effect on the contrast value. (Author abstract) 8 refs.

Sharma, V.K. (GEC Research Ltd, Wembley, Engl); Wheeler, M.J. *Semicond Sci Technol* v 2 n 11 Nov 1987 p 753-755.

**083207 CALIBRATION OF A GEL CHROMATOGRAPH FOR DETERMINING THE MOLECULAR WEIGHTS OF POLYMETHYL METHACRYLATE AND LITTLE STUDIED POLYMERS.** A method of calibrating retention volumes according to MM in GPC using specimens of any degree of polydispersion, characterized by any mean MM or intrinsic viscosity has been developed. The method is applied to PMMA, but because of the impaired resolution of the chromatographic column in the region of high MM, it was impossible to obtain a calibration plot in the form of a linear transformation of a PS calibration true for all values of the MM range. Two calibrations are obtained for the ranges  $M < 10^6$  and  $(0.7-3.0) \times 10^6$ . On the basis of these a single calibration plot was constructed for the whole MM range, which is a non-linear transformation of the PS calibration plot. (Edited author abstract) 14 refs.

**083208 INVESTIGATION OF RELAXATION PROCESSES IN LOW AND HIGH MOLECULAR WEIGHT BULK POLY(METHYL METHACRYLATE) BY DYNAMIC LIGHT SCATTERING.** Photon correlation functions of the polarized component of the scattered light from a low molecular weight PMMA have been studied in the temperature range 65-98°C. The observed relaxation functions have been represented by a multiexponential decay by using an inverse Laplace transform analysis. The computed spectrum of retardation times reveals a two-peak structure like that observed in the high molecular weight material ( $T_g = 107^\circ\text{C}$ ). The temperature dependences of the long-time peak associated with the primary glass-rubber relaxation in the two PMMA's are similar when compared at temperatures equidistant from their  $T_g$ 's. (Edited author abstract) 19 Refs.

## Morphology

**083209 MORPHOLOGY CHANGES AND VOLUME DEFORMATION OF INDIVIDUAL PHASES OF POLYMER BLENDS. FLUORESCENCE STUDIES OF POLYMER COLLOIDS. 9.** Fluorescence decay measurements were carried out on micron-size nonaqueous dispersions of poly(methyl methacrylate) (PMMA) particles sterically with polyisobutylene (PIB) and labeled in the PMMA phase with naphthalene (N) groups. The decays were nonexponential and mean decay times  $\langle \tau \rangle$  were intermediate between those of similar N groups in pure PMMA (53 ns) or PIB (43 ns) samples. These mean lifetimes  $\langle \tau \rangle$  decrease with increasing local N concentration. When samples of the dispersions in isooctane or hexadecane are annealed above 60°C, their room temperature  $\langle \tau \rangle$  values increase, and when powder samples are so annealed,  $\langle \tau \rangle$  decreases. These results point to the presence of an extensive PMMA-PIB interphase, with solvent swelling, and annealing leading to changes in the extent of interphases formation. (Edited author abstract) 7 refs.

## Optical Properties

**083210 EFFECT OF VARYING POLYMER MATRICES AND GASES ON THE SINGLET AND TRIPLET BEHAVIOR OF 2-PIPERIDINOANTHRAQUINONE.** The photophysical behavior of 2-piperidinoanthraquinone (2-PAQ) was studied by embedding the solute dye in a variety of polymer matrices like poly(methyl methacrylate) (PMMA), poly(ethyl methacrylate) (PEMA), polycarbonates (Lexan), polystyrene (PS), and epoxy resins all at room temperature. A simple experimental technique for preparing the polymer blocks containing the dyes in the shape of 5- or 10-mm thick blocks is described. Employing radiation of high input laser energy ( $\lambda = 532$  nm,  $450$  mJ/cm<sup>2</sup>), we have demonstrated the occurrence of cavitation in fluid solvents like benzene or toluene whereas in thin (1 mil) polymer films such a cavitation did not occur and only smooth triplet decay curves were seen. (Edited author abstract) 19 refs.

## Permeability

**083211 EFFECT OF TACTICITY ON PERMEATION PROPERTIES OF POLY(METHYL METHACRYLATE).** The effect of stereoregularity on gas permeation properties of poly(methyl methacrylate) (PMMA) was investigated. The gas permeability coefficients for He, H<sub>2</sub>, O<sub>2</sub>, N<sub>2</sub>, Ar, CH<sub>4</sub>, and CO<sub>2</sub> at 35°C near atmospheric pressure have been measured for three different PMMA's. Apparent diffusion and solubility coefficients were obtained from time lag data, and these were compared with data for a commercial PMMA previously reported. The permeability, solubility, and diffusion coefficients increase as the content of syndiotactic sequences increases. These observations are consistent with more dense packing of the isotactic form in the glassy state that stems in part from its lower glass transition temperature. The transport behavior for a 50:50 isotactic/syndiotactic blend was also studied. These so-called stereocomplexes exhibit permeation behavior comparable to other weakly interacting miscible blend systems. (Author abstract) 49 refs.

## Photochemical Reactions

**083213 THERMOLYSIS AND PHOTOCHEMICAL ACIDOLYSIS OF SELECTED POLYMETHACRYLATES.** Thermal behavior and thermolytic deprotection catalyzed by photochemically generated HSBF<sub>6</sub> in the solid state have been investigated for atactic polymethacrylates having benzyl,  $\alpha$ -methylbenzyl,  $\alpha,\alpha$ -dimethyl-

benzyl, and tert-butyl ester groups as well as cyclopropyl carbinol esters. It is shown that sensitivity of these polymethacrylates to photochemically induced acidolysis is very much reflected by the thermal deprotection temperatures except for the cyclopropyl carbinol esters, which possess the lowest deprotection temperature in the series but suffer from concomitant rearrangement to a thermally stable primary ester. The thermal rearrangement of the cyclopropyl carbinol ester, is more pronounced in the presence of acids. (Edited author abstract) 19 refs.

Itô, Hiroshi (IBM, San Jose, CA, USA); Ueda, Mitsuru. *Macromolecules* v 21 n 5 May 1988 p 1475-1482.

## Photoreactivity

**083214 PREPARATION OF THE POLYMER BEARING PENDANT QUINONOID GROUPS BY UV IRRADIATION AND ITS PHOTOCROSSLINKING.** In a previous paper we presented the mechanism of photocrosslinking of poly(methyl methacrylate) (PMMA) by bezoquinones. It was shown that the first step in the photocrosslinking was the photo-addition of the bezoquinones to PMMA and that the bound bezoquinones played an important role to promote the photocrosslinking between polymer chains in the next step. Therefore it is very interesting to prepare the polymers bearing quinone structure from the viewpoint of preparation of photocrosslinkable polymers. In this article, the photoreaction of copolymers of HEMA and MMA with tBQ was investigated and the contents of hydroquinone (HQ) units and benzoquinone (BQ) units in the copolymers were determined. Moreover the resulting polymer was proved to become photocrosslinkable by the treatment with p-benzoquinone. 3 refs.

**Physical Properties** See Also POLYMERS—Additives; POLYMERS—Physical Properties.

**083215 CHARACTERIZATION OF POLY(METHYL METHACRYLATE) PREPARED BY AQUEOUS POLYMERIZATION IN PRESENCE OF CORUNDUM.** The addition of corundum (Al<sub>2</sub>O<sub>3</sub>) in the aqueous reaction medium was found to catalyze the bisulfite-initiated polymerization of methyl methacrylate. The increase in its quantity led to an increase in conversion percentage and decrease in the viscosity average molecular weights up to addition of 1.5 g; then the conversion percentage was found to decrease and the viscosity average molecular weights were found to increase. The polydispersity of the polymer samples decreased when using initiator concentrations more than 0.2 mol/liter and increased on raising the reaction temperature. Thin layer chromatographic technique employed proved to be a good and rapid technique for giving an idea about the polydispersity of the polymers obtained under different reaction conditions. (Author abstract) 10 refs.

**083216 INFLUENCE OF THE TACTICITY OF POLY(METHYL METHACRYLATE) ON ITS MISCIBILITY WITH CHLORINATED POLYMERS.** Differential scanning calorimetry was used to determine the miscibility behavior of poly(methyl methacrylate) (PMMA)/chlorinated polymer blends. Nine PMMA's differing in tacticity were blended with three chlorinated polymers: poly(vinyl chloride) (PVC), a chlorinated PVC having a chlorine content of 68 percent (CPVC), and Saran, which is a random copolymer of vinyl chloride (12 percent) and vinylidene chloride (88 percent). The results

show that all these PMMA's are miscible with PVC, CPVC, and Saran under proper thermal treatment and especially at 298 K. (Edited author abstract). 48 Refs.

**083217 LIVING RADICAL POLYMERIZATION OF METHYL METHACRYLATE WITH TETRAPHENYLSUCCINODINITRILE AS A THERMAL INIFERTER.** The bulk polymerization of methyl methacrylate (MMA) with tetraphenylsuccinodinitrile (TPSN) at 60 approx. 80°C was found to proceed via a mechanism close to the living radical polymerization model proposed previously, i.e. both yield and molecular weight of the polymers increased with reaction time. However, the observed living radical nature was low. The MMA oligomer which can induce further radical polymerization was formed in the initial stage. (Edited author abstract) 17 refs.

**Pressure Effects**

**083218 SUSTAINED PRESSURIZATION OF POLYMETHYLMETHACRYLATE: A COMPARISON OF LOW- AND MODERATE-VISCOSITY BONE CEMENTS.** The effect of serially increasing sustained pressurization of two commercially available acrylic bone cements (Simplex-P and LVC) was evaluated in human cadaver femora. A new method for determination of the shear strength of the bone-cement interface in place of the traditional pushout tests was used. In this model, there was a significant increase in the bone-cement interfacial shear strength with increasing pressure, but no difference in the shear strength was found between the two cements. At all pressure levels, the shear strength of the cement was greater than that previously reported. Increased cement penetration into the cortical bone was demonstrated with increasing pressure and low-viscosity cement, but the extent of cement penetration did not correlate with the shear strength of the bone-cement interface. **Production**

**083219 POLYMETHACRYLATES (PMMA).** The market in PMMA semi-finished products is served by cast and extruded materials with somewhat different property profiles. In the preferred applications for the two materials there have been by and large no considerable changes since the last report. Surprisingly, the overall demand for cast PMMA in Europe, after stagnating, had been stimulated somewhat more strongly. The very interesting field and technology, of optical readable storage media has with PMMA as substrate. In the USA, a material Corian, Du Pont, (PMMA as resin matrix, but aluminium trihydrate as mineral component) has already been on the market for synthetic marblelike materials for a long time. It is marketed for simple sanitary ware and semi-finished sheet. PMMA with special flame retardant formulation, very good resistance to weathering, and outstanding optical appearance has proven very suitable for transparent noise barrier walls. The tendency is as everywhere in the plastics sector, to develop tailored or multifunctional products for the individual applications. 2 refs.

**Reactions**

**083223 STUDIES ON SOME RADICAL TRANSFER REACTIONS BY ENTRAPPING THE RADICALS AS POLYMER END GROUPS. II. REACTIONS OF OH RADICALS WITH AMINO ACIDS.** The reaction of OH radicals with a number of aliphatic amino acids has been studied by entrapping the resultant radicals as end groups of poly(methyl methacrylate) that have been detected and estimated by the sensitive dye partition technique. The rate constants of the reaction (in mol<sup>-1</sup> L S<sup>-1</sup>) of 7 amino acids at 25°C and at pH 1.00 have been determined. The change of pH did not produce any significant change in the end group profile of the polymer obtained, indicating no appreciable change in the rate of the reaction of OH radicals with the simplest amino acid glycine in the pH range studied. (Edited author abstract) 19 refs.

**083224 END GROUPS OF POLY(METHYL METHACRYLATE-co-STYRENE) PREPARED WITH tert-BUTOXY, METHYL, AND/OR PHENYL RADICAL INITIATION: EFFECTS OF SOLVENT, MONOMER COMPOSITION, AND CONVERSION.** The relative reactivities of tert-butoxy, methyl, and phenyl radicals toward styrene, methyl methacrylate, and several solvents (acetone, butan-2-one, toluene, and benzene) have been established by means of competition experi-

ments. These experiments demonstrate that when a source of tert-butoxy radicals is employed as the initiator for copolymerization and toluene or butan-2-one is used as the solvent, a majority of end groups may be solvent derived. This is a consequence of the tert-butoxy radicals' high propensity for hydrogen abstraction. Even with benzene as solvent, there is a significant proportion of solvent attack and resultant phenyl radical initiation. (Edited author abstract) 39 refs.

**083225 MOLECULAR MOTION OF THE PMMA CHAIN IN POLY(METHYL METHACRYLATE)/POLY(VINYLIDENE FLUORIDE) BLENDS BY SPIN TRAPPING LABELING.** Spin trapping is used to study molecular motion of PMMA chains in blends of poly(methyl methacrylate) poly(vinylidene fluoride) (PMMA/PVDF). Free radicals produced by thermal degradation of PMMA chains in the blends are trapped by 2,4,6-tri-tert-butylnitrosobenzene, and the spin-labeled chain ends are studied by electron spin resonance (ESR). The temperature dependence of the ESR spectra changes substantially as a function of the PVDF content of the blend. The narrowing curve of the outermost splitting widths and the generation curve of the mobile fraction of the spin label shift to low temperatures with increasing PVDF content of the blend. **083226 COMPLEXATION OF STEREOREGULAR POLY(METHYL METHACRYLATES). 11. A MECHANISTIC MODEL FOR STEREOCOMPLEXATION IN THE BULK.** The process of stereocomplexation between isotactic and syndiotactic PMMA in the bulk was studied by means of differential scanning calorimetry and wide-angle X-ray scattering as a function of annealing time and temperature. It appeared that in all cases the material obtained was partly crystalline. For low annealing temperatures the samples showed multiple endotherms with different characteristics. A mechanistic model, in which subsequent crystallization of the complexed chain sections plays an important role, is presented which accounts for the observed phenomena. (Edited author abstract). 34 Refs.

Schomaker, Elwin (State Univ of Groningen, Groningen, Neth); Challa, Ger. *Macromolecules* v 21 n 7 Jul 1988 p 2195-2203.

**083227 COMPLEXATION OF STEREOREGULAR POLY(METHYL METHACRYLATES). 12. COMPLEXATION PROCESS IN DILUTE SOLUTION.** The process of stereocomplexation between isotactic and syndiotactic PMMA in dilute solution was studied by means of differential scanning calorimetry of isolated complexed material, solution viscometry, and isothermal mixing calorimetry. The results were combined with results of investigations previously published. It appeared that essentially the same mechanism as proposed for the complexation process in bulk can account for the observed phenomena, including the previously reported association and aggregation stages following complexation. Two main processes are distinguished: complexation and subsequent crystallization of complexed chain sections, leading to the formation of complex particles. (Edited author abstract). 32 Refs.

**Sedimentation**

**083228 HYDRODYNAMIC AND TOPOLOGICAL INTERACTIONS IN SEDIMENTATION OF POLY(METHYL METHACRYLATE) IN SEMIDILUTE SOLUTIONS OF POLYSTYRENE IN THIOPHENOL.**

This work has been performed to clarify effects of two dynamical interactions, the hydrodynamic interaction and the topological interaction, on transport of a flexible chain molecule in the semidilute regime. The sedimentation velocity technique has been applied to obtain the sedimentation coefficient  $s$  of poly(methyl methacrylate). The effect of the topological interaction has been manifested on a master curve constructed, by use of the MW between entanglements,  $M_{e,PS}$ , from the  $s$  data after subtraction of the hydrodynamic screening effect. In solutions of PS with  $M_{PS} = 775,000$ , it has been found that a different transport mechanism may become dominant depending on both a ratio of  $M$  to  $M_{PS}$  and PS concentration. (Edited author abstract) 31 refs.

**083229 COMPARISON OF THE SEDIMENTATION DATA WITH THE HESS THEORY AND WITH SELF-DIFFUSION COEFFICIENT DATA OF POLYSTYRENE IN THE SEMIDILUTE REGIME AND IN MELTS.** The topological function  $\psi$ , obtained from analysis of sedimentation coefficient data of poly(methyl methacrylate) (PMMA) in semidilute solutions of high molecular weight (MW) polystyrene (PS) has been compared with a theory for self-diffusion of flexible polymers in the semidilute regime developed by W. Hess and also with  $\psi$  evaluated from tracer diffusion coefficient ( $D_{tr}^\infty$ ) data in the semidilute regime and from self-diffusion coefficient ( $D_s$ ) data in melts. It has been found that the Hess theory can reasonably well explain the observed dependence of  $\psi^{-1}$  on the ratio of MW of PMMA to MW between entanglements of PS,  $M_{e,PS}$ .  $\psi$  from  $D_{tr}^\infty$  data of a tracer PS in semidilute solutions of high MW PS has shown poor agreement with  $\psi$  from the  $s$  data. (Edited author abstract) 23 refs.

## Sheet

**083230 TEMPERATURE DEPENDENCE OF FRACTURE TOUGHNESS OF POLY(METHYL METHACRYLATE).** In this letter, the temperature dependence of the fracture toughness of PMMA, especially the variation around the  $\alpha$  relaxation temperature ( $T_g$ ), is reported. A poly(methyl methacrylate) cast sheet was used for this experiment. The measurements of the fracture toughness were carried out on a tapered double cantilever beam. The flexural modulus-temperature and the yield strength-temperature curves exhibited an obscure shoulder at 90°C. 7 refs.

## Solutions See Also GELS—Forming.

**083231 SEDIMENTATION BEHAVIOUR OF SEMI-DILUTE SOLUTIONS OF POLY(METHYL METHACRYLATE).** Sedimentation coefficients  $S$  of poly(methyl methacrylate) for a broad range of molecular weights  $M$  and concentrations  $1 \cdot 10^{-4} < c < 2 \cdot 10^{-1}$  (c in g ml<sup>-1</sup>) in the good solvent acetone at 20°C and the theta solvent acetonitrile at 35°C are reported. The results in the dilute regime are discussed in connection with those reported on poly(methyl methacrylate) and the many data available for polystyrene. Both sets of experimental results are compared with the scaling theory. (Edited author abstract) 20 refs.

**083232 CHAIN DYNAMICS OF POLY(METHYL METHACRYLATE) IN DILUTE SOLUTIONS STUDIED BY THE FLUORESCENCE DEPOLARIZATION METHOD.** Samples of poly(methyl methac-

rylate) (PMMA) labeled with anthracene in the middle of the chain were synthesized, and their local motions in dilute solutions were examined by the fluorescence depolarization technique. Theoretical functions based on various models for local motions were fitted to the data. The average anisotropy ratio became almost independent of the molecular weight above  $1.28 \times 10^5$ . At high viscosities or at low temperatures, the discrete conformation jump models such as the Jones-Stockmayer (JS) model and the generalized diffusion and loss (GDL) model were in good agreement with the experimental data compared with the models of diffusion on a continuous body such as the Bendler-Yaris (BY) model and the Skolnick-Yaris (SY) model. Plots of dynamic parameters of the Hall-Helfand (HH) model versus viscosity revealed nondiffusive small-scale motions in the higher viscosity region. (Edited author abstract) 43 refs.

Sasaki, Takashi (Kyoto Univ, Kyoto, Jpn); Yamamoto, Masahide; Nishijima, Yasunori. *Macromolecules* v 21 n 3 Mar 1988 p 610-616.

**083233 COMPARISON OF THE TRANSLATIONAL DIFFUSION OF LARGE SPHERES AND HIGH MOLECULAR WEIGHT COILS IN POLYMER SOLUTIONS.** The translational diffusion of large stearic acid coated silica spheres ( $R_H = 1595$  Angstrom) and high molecular weight polystyrene (PS) fractions in poly(methyl methacrylate) (PMMA) solutions has been examined by using dynamic light scattering (QELS) over the dilute/semidilute concentration ranges of the latter polymer. When the PMMA concentration is normalized by the overlap concentration,  $C^*$ , the reduced diffusion coefficient ( $D/D_0$ ) for the sphere is a universal function of  $C_{PMMA}$ . A similar observation applies to the data for the PS fractions. This is in accord with scaling predictions. The results indicate that there may be a significant coupling of the dynamics of the probe chain and those of the network polymer. (Edited author abstract) 5 refs.

## Spectroscopic Analysis

**083235 EFFECT OF NMR SIGNAL FROM INITIATOR FRAGMENT ON TRIAD TACTICITIES OF POLY(METHYL METHACRYLATE)S FORMED BY 2,2'-AZOBISISOBUTYRONITRILE AND BENZOYL PEROXIDE.** It was reported that tacticity of the poly(methyl methacrylate) (PMMA) prepared with benzoyl peroxide (BPO) deviated slightly from Bernoullian statistics while that of PMMA formed by 2,2'-azobisisobutyronitrile (AIBN) was consistent with the Bernoullian. In this work we found using the 500MHz <sup>1</sup>H NMR spectra of the PMMA from AIBN that the two small methyl proton signals of equal intensities attributed to the initiator fragment, (CH<sub>3</sub>)<sub>2</sub>C(CN)- at the  $\alpha$ -end of the chain overlap indistinguishably with the isotactic and heterotactic  $\alpha$ -methyl proton signals, respectively, in the <sup>1</sup>H NMR spectra measured at lower frequency, namely, 100 MHz. 9 refs.

**083237 IDENTIFICATION OF DYES IN SOLID POLY(METHYL METHACRYLATE) BY MEANS OF LASER DESORPTION FOURIER TRANSFORM ION CYCLOTRON RESONANCE MASS SPECTROMETRY.** Laser desorption (LD) is a pulsed ionization source for which the pulsed Fourier transform ion cyclotron resonance (FT/ICR) mass spectrometer is the detector of highest mass resolution. In this paper, we show that LD/FT/ICR can detect and identify (by chemical formula) dyes in solid poly-(methyl methacrylate) (PMMA) commercial plastics at concentrations at least an order of magnitude lower (0.1% vs 1-2% by weight) than those obtained by the best currently available alternative method (attenuated total reflectance Fourier transform infrared spectrometry). Both untreated and redissolved PMMA have been characterized, in the presence and absence of up to three dyes in a single sample. (Edited author abstract) 44 refs.

**083238 RELAXATIONAL TRANSITIONS IN POLYMETHYLMETHACRYLATE AS SHOWN BY RELAXATIONAL SPECTROMETRY.** Attention in this work was focussed on the group of  $\gamma$ -transitions. It was found that below the  $\alpha$  and  $\beta$  transitions not four but five relaxational transitions are observed. This is connected with the fact that in presence of dissolved water adsorbed on the macromolecules a new relaxational  $\mu$ -transition appears in PMMA. It disappears in the dry polymer. The appearance of such transitions linked with the presence of water is characteristic of many hydrophilic polymers. To find the relaxation constants of these transitions (activation energy  $U_i$  and the pre-exponential coefficient  $B_i$ ) in the Boltzmann-Arrhenius equation allows us to construct the dependence in the coordinates  $1/T_i \cdot \log v$  for all the relaxational transitions. From the data of mechanical and structural relaxation, the author analyzes 13 different relaxational transitions in polymethylmethacrylate below and above the glass transition point. The nature of the individual transitions is considered and a classification proposed. (Edited author abstract) 28 refs.

**083239 XPS STUDY OF BOUNDARY PHASE STRUCTURE BETWEEN STEREOREGULAR POLY(METHYL METHACRYLATE) AND POLY-AMIDE SUBSTRATE.** The purpose of this work is to elucidate the boundary phase structure between nylon-6 (Ny) substrate and PMMA in relation to the difference in tacticity of PMMA by X-ray photoelectron spectroscopy (XPS). Ny was shown to be usable as a model compound for Kevlar-fiber from the Fourier-transform infrared spectroscopy. The characteristic ratios for atactic, syndiotactic and isotactic PMMA were obtained as 7.5, 7.3, and 10.3 from the solution properties in tetrahydrofuran and as 7.9, 9.2, and 10.7 from the bulk properties, respectively.

These data show that isotactic PMMA is more extended in the unperturbed state or more restricts the rotation of molecular chain compared with atactic and syndiotactic PMMA. 8 Refs.

**Structure** See Also POLYURETHANES—Structure.

**083241 LIQUID CRYSTALS FROM POLY(4,4'-METHOXYBIPHENYL) METHACRYLATE.** Side-chain liquid crystalline poly(4,4'-biphenyl) methacrylate was studied by x-ray diffraction. Three smectic phases were described using a ribbon-like structural model for the polymer chain. In the smectic  $S_p$  phase, ribbons lie flat on their sides to form layers with a spacing equal to the thickness of the ribbons. In the smectic  $S_A$  phase, the ribbons stand upright giving layers with a thickness corresponding to the length of one extended monomeric unit. In the ordered smectic  $S_C$  phase, the layer thickness also corresponds to one extended repeat unit, and the pendant groups are arranged according to a two-dimensional oblique lattice. The Schlieren texture observed in the  $S_p$  phase was analyzed in terms of symmetry. (Author abstract) 12 refs.

## Surfaces

**083242 SURFACE LAYER THICKNESS IN NON-AQUEOUS POLY(METHYL METHACRYLATE) DISPERSIONS. II. STABILIZATION WITH THE DIBLOCK COPOLYMER POLY(STYRENE-B[ETHYLENE-CO-PROPYLENE]).** Well-defined non-aqueous dispersions of poly(methyl methacrylate) in n-heptane, and in a binary liquid mixture of n-heptane and n-propanol, have been stabilized by the diblock copolymer poly(styrene-b[ethylene-co-propylene]) having a narrow molar mass distribution. The thickness of the surface layer was determined from viscosity studies of the dispersions at 298, 308, and 318 K. Solution viscosities of a narrow distribution standard of ethylene-propylene copolymer in n-heptane, and in the binary liquid mixture, at 298, 308, and 318 K were obtained in order to estimate the root-mean-square end-to-end distance of free ethylene-propylene copolymer chains. (Edited author abstract) 23 Refs.

## Swelling

**083243 METHANOL TRANSPORT IN PMMA: THE EFFECT OF MECHANICAL DEFORMATION.** The effect of cold work on the transport of liquid methanol in crosslinked PMMA disks has been determined at temperatures from 35-56°C. Deformed samples absorb at fast rates with kinetics that approach those of

Fickian diffusion. Undeformed samples sorb at lower rates and the kinetics tend toward those of Case II transport. Shape recovery accompanied swelling in deformed samples. Samples saturated with methanol were desorbed in cyclohexanol. Resorption of desorbed samples showed fast rates for both deformed and undeformed samples and matched those of the absorption cycle in deformed samples. An analogy is made between the microstructure due to cold work and due to swelling. (Author abstract) 38 refs.

**Synthesis** See Also VINYL RESINS—Photochemical Reactions; VINYL RESINS—Synthesis.

**083244 STEREOCHEMISTRY OF THE OLIGOMERIZATION OF METHYL METHACRYLATE BY  $t\text{-C}_4\text{H}_9\text{MgBr}$  IN TOLUENE AT  $-78^\circ\text{C}$ .** Recently, we found that the polymerization of MMA by  $t\text{-C}_4\text{H}_9\text{MgBr}$  in toluene at  $-78^\circ\text{C}$  was a completely living and highly isotactic-specific system. The  $\alpha$ - and  $\omega$ -end tacticities of the PMMA were studied by 2D NMR techniques. In this work, isotactic oligo(MMA)s were prepared by the polymerization of MMA with  $t\text{-C}_4\text{H}_9\text{MgBr}$  in toluene at  $-78^\circ\text{C}$  and their configurational sequences were investigated in detail by gel permeation chromatography and 2D NMR spectroscopy to gain a more detailed understanding of stereoregulation in polymerization. 22 refs.

Hatada, Koichi (Osaka Univ, Toyonaka, Jpn); Ute, Koichi; Tanaka, Katsuji; Kitayama, Tatsuki. *Polym J* v 19 n 11 1987 p 1325-1328.

**083245 STEREOREGULARITY OF POLY(METHYL METHACRYLATE) PREPARED BY AQUEOUS POLYMERIZATION AND CATALYZED BY CORUNDUM.** The aqueous polymerization of methyl methacrylate was carried out in the absence and in the presence of corundum or carborundum at 25 and  $80^\circ\text{C}$ . In the absence of corundum and carborundum, it has been found that increasing the polymerization temperature from 25 to  $80^\circ\text{C}$  resulted in changing the tacticity of the obtained polymers. At  $25^\circ\text{C}$ , the isotactic triad was 26% while the heterotactic triad was 33.5% and the syndiotactic one was 40.5%. Increasing the polymerization temperature to  $80^\circ\text{C}$  resulted in a decrease of the isotactic structure to 0% and increased the heterotactic structure and syndiotactic structure to 48 and 52% respectively. Raising the polymerization temperature to  $80^\circ\text{C}$  in the presence of the same amount of corundum resulted in an increase in both the isotactic and heterotactic triads to 35 and 32.7%, respectively. Polymerizing at  $80^\circ\text{C}$  in presence of corundum resulted in nearly an equal percentage of each triad. (Edited author abstract) 21 refs.

**083246 GRAFTING OF GELATIN DURING POLYMERIZATION OF METHYL METHACRYLATE IN AQUEOUS MEDIUM.** When methyl methacrylate is polymerized in aqueous medium in the presence of gelatin, graft copolymer macromolecules with gelatine backbones and poly(methyl methacrylate) (PMMA) grafts are formed. Due to the presence of graft copolymer, polymolecular micelles consisting of about 100 macromolecules are created. These micelles prevent macroscopic precipitation of PMMA. Fractionation in demixing solvents has been used to separate the components of the polymerization mixture, and the light-scattering method has been employed to determine their molecular weights. Each grafted macromolecule carries about one graft. The hypothesis of random grafting from gelatin backbones seems to explain most of the experimental observations. (Author abstract) 41 refs.

**083247 POLYMERIZATION OF METHYL METHACRYLATE IN MICELLAR PHASE: A KINETIC STUDY.** Polymerization of methyl methacrylate (MMA) using  $\text{Ce(IV)}$  as initiator in aqueous nitric acid solution in the presence of sodium lauryl sulfate (NaLS) has been studied kinetically at a temperature range of 25-35°C. The rate of polymerization ( $R_p$ ) increases with increasing concentration of NaLS, and it was also proportional to  $[\text{MMA}]^2$ ; but, in the presence of NaLS, the change of  $R_p$  with respect to  $[\text{Ce(IV)}]$  and  $[\text{H}^+]$  were not linear and similarly the rate of  $\text{Ce(IV)}$  disappearance was not proportional to its original concentration. The overall activation energy of the polymerization process in presence of 0.01M NaLS was found to decrease by approximately 7.0 kcal  $\text{mol}^{-1}$ . The monomer-micelle association constant has been calculated to be  $5.134 \times 10^4 \text{ mol}^{-1} \text{ L}$ . The polymer obtained in surfactant medium is sparingly soluble in benzene and DMSO. From infrared spectra clear evidence of vinyl polymerization was obtained. (Edited author abstract) 9 refs.

Panda, Rahas B. (Sambalpur Univ, Jyoti Vihar, India); Patel, N.; Sinha, B.K. *J Appl Polym Sci* v 35 n 8 Jun 1988 p 2193-2200.

**083248 EFFECT OF PRESSURE ON THE PRECIPITATION AND SOL-PHASE AQUEOUS POLYMERIZATION OF METHYL METHACRYLATE.** Effect of pressure (atmospheric to 120 kg/cm<sup>2</sup>) on the  $\text{K}_2\text{S}_2\text{O}_8\text{-Na}_2\text{S}_2\text{O}_4$ -initiated aqueous polymerization of methyl methacrylate has been studied at 25°C. When the concentrations of the redox initiator are so adjusted as to obtain the separating polymer phase as a coarse coagulum, the conversion, rate, and molecular weight of polymerization tend to rise initially with increase of pressure up to a certain value and fall subsequently to a limiting value. However, these parameters fall monotonously with an increase in pressure when the polymer phase separates out as a fine colloid at a lower concentration of the initiator. The fall in the molecular weight with pressure is explained on the basis of enhanced monomer transfer. In the colloidal range the pressure dependence trend is related to the stability of the colloidal phase. The rate is proportional to the square root of the product of  $\text{K}_2\text{S}_2\text{O}_8\text{-Na}_2\text{S}_2\text{O}_4$  and varies linearly as the first power of the monomer concentration. (Edited author abstract) 16 refs.

## Testing

**083249 INSTRUMENTED FALLING WEIGHT IMPACT TESTING OF PMMA.** Instrumented falling weight impact tests have been conducted on polymethylmethacrylate (PMMA), a model material for the application of linear elastic fracture mechanics. It is shown that the siting of a force transducer has considerable effect on the results. With the transducer attached to the falling weight, signals simply reflected resonances within the system. Attempts to filter the signal either electrically or digitally failed to extract meaningful information, and were abandoned in favor of incorporation of the transducer in the solid base of the equipment. (Edited author abstract) 14 refs.

## Thermal Effects

**083250 THERMAL DEGRADATION OF SATURATED POLY(METHYL METHACRYLATE).** The author has determined the Arrhenius activation parameters for degradation of saturated PMMA. We believe this is the first accurate determination of these parameters for PMMA. By studying the degradation of low molecular weight PMMA (so that  $\text{zip} \gg \text{DP}$ ) that is completely saturated and has a narrow polydispersity, we have determined accurate Arrhenius parameters for random chain scission in PMMA. Experimental evidence shows that the process occurs with an Arrhenius preexponential

factor of approx.  $2 \times 10^{16} \text{ s}^{-1}$ . 11 refs.

## Thermodynamic Properties

**083251 ADIABATIC HEATING IN POLY(METHYL METHACRYLATE) AT HIGH HYDROSTATIC PRESSURES.** Recently we reported the adiabatic method to determine the temperature changes in poly(methyl methacrylate) (PMMA) resulting from the rapid application of hydrostatic pressures at different reference temperatures. In that report the ratio of the temperature change to the pressure change was represented by a quadratic equation. In this note we report the analysis of our experimental results for poly(methyl methacrylate). It is shown that thermoelastic experiments dealing with adiabatic heating under rapid applications of hydrostatic pressures afford a new approach to evaluate important thermal properties of viscoelastic materials. 16 refs.

**POLYOLEFINS** See Also POLYAMIDES—Mechanical Properties; THERMOPLASTIC ELASTOMERS—Mechanical Properties.

## Antioxidants

**083252 ANTIOXIDANTS.** Polyolefins are usually process stabilised using a blend of phenolic antioxidants with phosphites and phosphonites. Long-term heat stability is achieved principally with high molecular weight phenolic antioxidants possibly in combination with thioether-based synergists. A more recent development of this kind is based on the increasing use of high molecular weight sterically hindered amines (HALS - hindered amine light stabilisers). Antioxidants are generally used in concentrations of between 0.03 and 0.3% w/w although higher levels may be required for special applications. It is expected that the long established commercial antioxidants will maintain their market dominance. Additional blends of phosphites with phenolic antioxidants will be introduced. For reasons of handling safety, non-dusting grades will increase in importance. Market segmentation will continue and antioxidant-stabiliser systems will be made available to meet specific requirements in special applications. High molecular weight HALS, i.e., light stabilisers, will probably be utilised increasingly to increase the thermal stability of polyolefins in particular. 9 refs.

Gugumus, F. *Kunstst Ger Plast* v 77 n 10 Oct 1987 p 84-86.

**083253 THE MECHANISM OF THE EFFECT OF HINDERED AMINES ANTIPHOTOOXIDATION OF POLYOLEFINE.** The effects of a model piperidine compound, 2,2,6,6-tetramethyl-piperidine (I), and its corresponding N-oxyl derivative, 2,2,6,6-tetramethyl-piperidinoxy, free radicals (II), on scavenging free radicals, decomposing hydroperoxide and quenching of the excited state were examined. Both compounds can scavenge the free radicals generated from cleavage of the initiator AIBN, but the effect is not significant. Both (I) and (II) can decompose t-BuOOH and play an important role in the antiphotooxidation of the polyolefines. The results imply that there is a multifunctional role played by hindered amines in protecting the light sensitive polyolefines from photodegradation. (Edited author abstract). 4 Refs.

## Crosslinking

**083254 METHODS AND BENEFITS OF CROSSLINKING POLYOLEFINS FOR INDUSTRIAL APPLICATIONS.** The silane grafting route to the crosslinking of polyolefins can open up wide areas of application not easily attained by the conventional techniques of peroxide addition or irradiation. The thermal limitations on processing and cure rates imposed by the former; and the high capital cost, thickness and shape limitations imposed by the latter are dispelled when a two step grafted system is employed. The technology involves the chemical grafting of an easily hydrolysable vinyl silane onto a polyolefin chain. This paper outlines property levels attainable with specific reference to well established as well as developing areas of application. A wide range of products is covered including electrical cable insulation, hot water pipe, adhesives, floorings, foams, heat shrink products and packaging. (Edited author abstract)

## Crystallization

**083255 X-RAY INVESTIGATIONS OF THE FORMATION OF CORE-FIBRILS CRYSTALLIZED OUT OF THE ORIENTED MELT.** Crystallization models for the formation of core-fibrils crystallized from the oriented melt are discussed by comparing results from X-ray experiments with theoretical predictions. The systems isotactic polypropylene-poly (1-butene) and isotactic polypropylene - atactic polypropylene have been chosen. From wide angle X-ray scattering, the thicknesses of the core-fibrils, lattice distortions, and unit-cell parameters have been determined. Interface distribution functions have been used to evaluate the axial morphology of the fibers from meridional small angle X-ray scattering curves. It appears that the morphological predictions made by the crystallization models of Pennings and of Hoffman cannot be confirmed by the experimental findings. The diffusion model proposed by Petermann partially describes the morphological properties of the core-fibrils. (Edited author abstract) 25 refs.

**083256 OXIDATION OF HINDERED AMINE LIGHT STABILIZERS TO NITROXY RADICALS IN SOLUTION AND IN POLYMERS.** Cyclohexane and three polyolefins (PE, PP and EPM) have been oxidized by  $\gamma$ -irradiation, and the concentration of nitroxyl radicals derived from a typical HALS added either before or after irradiation has been studied by ESR spectroscopy. The results indicate that HALS is rapidly oxidized by peroxy radicals under irradiation and that afterwards it can be oxidized more slowly by hydroperoxides. This last reaction is, however, very limited. (Author abstract) 13 refs.

## Filaments

**083257 POLYOLEFIN FIBRILS OBTAINED FROM HIGH PRESSURE SPINNING AND THEIR PAPER-LIKE SHEETS FORMED BY SOLVENT PROCESS.** The production process of microfibrillar materials or fibrils in which polyolefinic polymers are spun through an orifice under high temperature and high pressure is called flash spinning. A study was made to determine the high strength fibril producing conditions by dry-spinning a solution of polypropylene in dichlorometh-

ane through an orifice at high temperature and high pressure. The water system used in conventional paper forming processes is not applicable in forming a sheet of polyolefin fibrils. In order to develop a solvent system for a sheet forming process capable of dealing with hydrophobic fibrils, a comparative study of various solvents was made to determine how the solvent might facilitate the sheet-forming operation. Solvents having solubility parameters near those of polypropylene promoted the formation of paper-like sheets of fibrils with satisfactory physical properties. ## Fillers

**083258 SYNTHESIS OF ALUMINOTITANATE DRESSINGS FOR FILLED POLYOLEFIN COMPOSITIONS.** The authors have developed complex aluminotitanate dressing agents. The compounds are viscous liquids or waxy solids with relatively low melting points; they are soluble in most organic solvents and are sufficiently resistant to hydrolysis. The compounds were prepared by reacting a mixture of tetraalkyltitanate and trialkyl-aluminate with a higher aliphatic acid in the required ratio in an aromatic solvent, with simultaneous azeotropic distillation of the alcohols formed in the ester interchange. The dressing activity of the aluminotitanate acylates was evaluated on the system liquid petrotulatum-aluminum hydroxide (filler content 50 mass%), used to simulate polyolefin compositions with high filler contents. It is shown that preliminary modification of the aluminum hydroxide with the synthesized compounds (1% of the filler mass) efficiently reduces the dynamic viscosity of the compositions: at minimum shear rates the viscosity of the system decreased approximately by a factor of 100. 10 refs.

## Film See PLASTICS FILMS—Surface Properties.

## Flame Resistance

**083259 USE OF WATER-GROUND MICA IN POLYOLEFINS.** Highly delaminated muscovite mica products (WG-1 and WG-2) have been developed by J.M. Huber Corp. The micas are characterized as a 325-mesh product having high brightness and very narrow particle size distribution. At 40% loading in polypropylene, WG-1 mica provides substantial improvement in tensile modulus and equal tensile strength to unfilled polymer; in high-density polyethylene (HDPE), WG-1 provides four times the tensile modulus and a 50% increase in tensile strength over unfilled polymer. Surface modification of the water-ground mica (SM) provides substantial improvement in tensile strength over untreated mica at greater than 20% loading in polypropylene; in HDPE, tensile strength is twice that of unfilled polymer. (Author abstract) 3 refs.

## Foam

**083260 COMPRESSION MODULI OF SOME PMP MICROCELLULAR FOAMS.** The elastic moduli of poly(4-methyl-1-pentene) foams made by several processes are measured. The results reveal that several terms need to be added to the currently accepted mathematical representation. Thus, the amount of noncontributing mass and the efficiency of the contributing mass must be considered along with the isotropic reduction in total mass. The mathematical equation derived gives new insight into the structure and properties of microcellular foams. (Author abstract) 9 refs.

## Injection Molding

**083261 PROJEVY STRUKTURY REALNYCH VYSTRIKU Z POLYOLEFINU.** [Manifestations of Structure in Polyolefin Injection Mouldings]. Gate area structure of real HDPE and PP injection moldings of an intricate shape was investigated by light microscopy in polarized light. Three types of arrangements were distinguished in this particular area, namely closed, half-open, and open interconnections of layers. Such an arrangement gives rise to a greater number of defects depending on process and design conditions. Also, the gate region of the injection moldings studied turned out to be the only sensitive place capable of responding structurally to changes in technology. (Edited author abstract) In Czech. 3 refs.

**083263 PROPERTY CORRELATIONS FOR DOUBLY ORIENTED POLYMERS PREPARED BY THE ROLLTRUSION TECHNIQUE.** The authors comment on some of the salient features which have been found for polyethylene and polypropylene and which have not yet been emphasized. Tensile strength and wear behavior are chosen to illustrate relationships. It is apparent that the trends observed in these engineering properties can be related primarily to changes in the 'amorphous' intercrystallite regions of the materials, the orientation and properties depending primarily upon processing conditions. 17 refs.

Magill, J.H.; Sun, D.C.; Shankernarayanan, M.J. *J Appl Polym Sci* v 34 n 6 Nov 5 1987 p 2337-2343.

**083264 MECHANICAL PROPERTIES AND MOLECULAR MOBILITY IN ORIENTED POLYOLEFINS.** The temperature dependence of the static elastic modulus and correlation time of rotation of 2, 2, 6, 6-tetramethylpiperidine-1-oxyl has been studied at  $210 < T < 370$  K for oriented films of isotactic polypropylene and low- and high-density polyethylene. A parallel trend has been demonstrated in the changes in elastic modulus and correlation time of rotation during the heating and orientation of the polymer, which is evidence that the most defective part of the amorphous phase where

the probes are located plays an important part. The proportion of tie chains has been assessed and does not exceed 7%. (Author abstract) 20 refs.

## Melting

**083265 HEAT OF FUSION OF POLY(4-METHYLPENTENE-1).** The heat of fusion of perfectly crystalline poly(4-methylpentene-1) (P4MP1),  $\Delta H_u$ , has been determined by two methods. Melting point depressions (A) in concentrated solutions in naphthalene and cyclododecane, and in infinitely dilute solutions in 39 solvents, led to  $\Delta H_u = 5.5 \pm 0.3$  kJ mol<sup>-1</sup> ( $65 \pm 4$  J g<sup>-1</sup>). The second method (B) involved new measurements of the crystalline volume  $V_{uc}$  as a function of temperature, in order to calculate  $\Delta H_u$  from the Clausius-Clapeyron equation: extrapolation to the melting point gave  $V_{uc} = 109.2$  cm<sup>3</sup> mol<sup>-1</sup>. There is at present no reason to prefer one set of values to the other, although the degree of crystallinity estimated from the low  $\Delta H_u$  and the experimental heat of fusion is in the 75-85% range, in excellent agreement with x-ray diffraction data. Depending on the selected  $\Delta H_u$ , the entropy of fusion is either similar or lower than for other branched polyolefins. The results are discussed in terms of order in the melt, order seemingly relevant to the understanding of the mechanism of formation of the noncrystalline thermoreversible gels of P4MP1. (Edited author abstract) 45 refs.

## Microstructure

**083266 ETHYLENE-CHLOROTRIFLUOROETHYLENE COPOLYMERS. II. EFFECTS OF STRUCTURE ON RESISTANCE TO THERMAL STRESS CRACKING.** Copolymers of ethylene and chlorotrifluoroethylene that contain small amounts of units derived from perfluorohexylethylene show improved resistance to thermal stress cracking. This is a consequence of effects of these units on structural parameters of both the crystalline and amorphous phases. Those of the crystalline phase entail growth and organization of lamellae, whereas those of the amorphous phase are related to conformation and packing of polymer chains. The crystalline phase consists exclusively of alternately arranged units of ethylene and chlorotrifluoroethylene. The amorphous phase is characterized by chain segments composed of randomly distributed units derived from ethylene, chlorotrifluoroethylene, pairs of these two units, and units derived from perfluorohexylethylene. (Author abstract) 3 refs.

## Molecular Structure See POLYPROPYLENE—Radiation Effects.

## Molecular Weight

**083267 MOLECULAR WEIGHTS OF POLYETHYLENE AND POLYPROPYLENE BY VAPOR PRESSURE OSMOMETRY AT ELEVATED TEMPERATURES.** The Wescan Model 232-A VPO was modified with a 12-volt regulated power supply for supplying bridge current and with thermocouples to allow for direct digital readout of the syringe box and measuring chamber temperatures. The modified instrument was used to measure number-average molecular weights ( $M_n$ ) of standard (NBS) polyethylenes. Agreement with NBS values was good (within 10%) for  $M_n < 3 \times 10^4$  and fair (within 20%) for  $M_n = 1 \times 10^5$ . Results on  $M_n$  of commercial polypropylenes are also reported. (Author abstract) 3 refs.

## Oxidation

**083268 ON THE NATURE OF PURPLE HYDROCARBON - THE OXIDANT FOR POLYOLEFINS.** Phase-transferred permanganate is found to be an oxidant for polyolefins. The nature of this oxidant, which is an ion pair comprising a lipophilic cation and permanganate ion—depends upon the catalyst cation used. The lower is the stability constant, the greater is the oxidizing capacity. (Edited author abstract) 7 refs.

Konar, J. (IIT, Kharagpur, India); Ghosh, R.; Banthia, A.K. *Polym Commun (Guildford Engl)* v 29 n 2 Feb 1988 p 36-37.

**083269 MODEL STUDIES OF THE INTERACTION OF Cu<sup>2+</sup> IONS WITH ETHANEDIOIC ACID BIS[(1-PYRENYLMETHYLENE)HYDRAZIDE].** The chelating properties of ethanedioic acid bis[(1-pyrenylmethylene)hydrazide] (OAPH) with Cu<sup>2+</sup> and Pb<sup>2+</sup> in solution are investigated by fluorescence quenching measurements. In ethanol, the formation of ground-state complexes is observed with association constants of  $K_c = 1.5 \times 10^6$  M<sup>-1</sup> and  $1.3 \times 10^6$  M<sup>-1</sup> for Cu<sup>2+</sup> and Pb<sup>2+</sup>, respectively. Pb<sup>2+</sup> ions retard the excimer-like emission of OAPH in favor of monomer emission, indicating a conformational change upon chelation. The importance of these results in determining the mechanism of the inhibition of Cu<sup>2+</sup> catalyzed thermal oxidation in polyolefins by the addition of bis-hydrazides is discussed. (Author abstract) 44 refs.

Blatt, Edward (CSIRO, Melbourne, Aust); Hodgkin, Jonathan; Loder, John; Mau, Albert W.-H.; Sasse, Wolfgang H.F.; Ghiggino, Kenneth P. *Polym Degradation Stab* v 20 n 1 1988 p 75-88.

**083270 OXIDATION PROCESSES IN BLUE WATER PIPE.** The thermal, hydrolytic and photochemical oxidation of blue water pipe material has been studied using Fourier Transform infra-red microscopy, differential scanning calorimetry (DSC) and hydroperoxide analysis. The results indicate that oxidation of the pipe occurs predominantly on the outer surface and to a lesser extent on the bore, often with little or no change in the middle layers. FTIR analysis of microtomed sections of the pipe supports the DSC analysis (oxidation induction time at 200°C - OIT) and indicates leaching and consumption of the polymer antioxidants at the outer surface of the pipe. Oxidation profiles at 80°C in water, as measured using carbonyl index, indicate an unusual hydrolytic oxidation and extraction of the carboxylic oxidation products only at the outer pipe surface to a depth of about 0.5 mm resulting in high hydroperoxidation levels. These oxidation analyses are consistent with density profile changes through the pipe. (Edited author abstract) 7 refs.

## Physical Properties See Also POLYMERS—Physical Properties.

**083271 RHEOLOGICAL PROPERTIES AND CRYSTALLINE STRUCTURE OF THE DYNAMICALLY CURED EPDM AND PP/HDPE TERNARY BLENDS.** The rheological properties and crystalline structure of the polyolefin ternary blends of EPDM/polypropylene/high density polyethylene were studied. Blends were prepared in a laboratory internal mixer by two different methods. In blend-cure process, blending and curing were performed simultaneously and EPDM was cured by dicumyl peroxide (DCP) in the presence of PP/HDPE under shear. The cure-blend was to cure EPDM alone first under shear (dynamic curing) and then mix the cured EPDM with P and HDPE. The effect of

DCP concentration, intensity of the shear mixing, and the rubber/plastic composition were studied using capillary rheometer and X-ray diffractometer. The PP-rich ternary blends showed the effect of the mechanooxidative degradation of PP by shear and peroxide. The melt viscosity increased with increasing DCP concentration in blends of EPDM-rich compositions. (Edited author abstract) 21 refs.

Ha, Chang Sik (Pusan Natl Univ, Pusan, South Korea); Kim, Sung Chul. *J Appl Polym Sci* v 35 n 8 Jun 1988 p 2211-2221.

**083272 MORPHOLOGY AND RHEOLOGICAL PROPERTIES OF POLYPROPYLENE-LINEAR LOW DENSITY POLYETHYLENE BLENDS.** The dynamic shear viscosity and the morphology of polypropylene homopolymer and copolymer blended with linear low density polyethylene are studied. A maximum in the dynamic shear viscosity vs. blend composition is reported for the polypropylene copolymer, linear low density polyethylene system. The increasing dynamic shear viscosity is in accordance with the occurrence of a morphology of polyethylene inclusions in rubber surrounded by a polypropylene matrix. (Edited author abstract) 39 refs.

## Radiation Effects

**083274 STRUCTURAL CHANGES INDUCED BY  $\gamma$ -RAYS ON MODEL LINEAR ETHYLENE-BUTENE COPOLYMERS.** Well characterized model copolymers are used to study the effects of ionizing radiation. Linear copolymers of ethylene and butene-1 with uniform chemical microstructure and very narrow molecular weight distributions are irradiated at room temperature with  $\gamma$ -rays from a  $^{60}\text{Co}$  source. Changes in the molecular hydrodynamic volume can be readily detected by GPC. Changes in molecular weight averages  $M_n$  and  $M_w$  are measured by membrane osmometry and light scattering. Cross linking seems to be the main effect of radiation and chain scission is negligible up to the gel point. The very uniform molecular structure and size in the non-irradiated polymer allows for the use of a completely general model to correlate changes in molecular weight averages and branching. The model is suitable for linear polymers with reactive groups randomly distributed along the chain, and contains no simplifying approximations. (Author abstract) 23 refs.

## Stability

**083276 MECHANISM OF SYNERGISTIC STABILIZATION BY HINDERED AMINES.** Tetramethyl piperidine (TMP) and several derivatives have been studied for their activities in various modes of polymer stabilization. The derivatives are tetramethyl piperidinoxyl (TMPO), N-hydroxy tetramethyl piperidine (TMPOH), N-butoxy tetramethyl piperidine (TMPOB) where R is n-butyl and t-butyl, and N-methyl tetramethyl piperidine (TMPOMe moiety of Tinuvin 292) as well as some commercial HALS (hindered amine light stabilizer). The results showed that all the TMP derivatives, with perhaps the lone exception of TMPOB, exhibit individually only modest stabilization of some kind. For certain stabilizer functions there are combinations of compounds which are strongly synergistic. If these derivatives were produced during processing or aging of polyolefins containing HALS, their combined actions could explain the outstanding effectiveness of HALS. (Edited author abstract) 58 refs.

## Stabilizers

**083277 STABILIZATION OF POLYOLEFINS FOR APPLICATIONS IN EXTRACTIVE MEDIA.** Polyolefins have long passed the stage where they were regarded as a low-price material for short-life articles with throwaway character. By developing efficient antioxidants and sophisticated formulations, it has become possible to control one of their major disadvantages, namely the oxidation sensitivity during processing and long-term service. An interesting combination of interesting technological properties such as good processability due to low melt viscosity, considerable hardness and stiffness in the cooled stage, high toughness and elasticity, high chemical resistance and good slip properties has opened the way for polypropylene (PP) and high density polyethylene (HDPE) into fields of application which can certainly be described as 'high-performance'. In numerous cases, polyolefins used as container materials or as a component part of transport systems are not only exposed to oxygen-containing atmosphere, but are temporarily or over their entire service life exposed to a more or less pronounced extraction behaviour.

Pfahler, G.; Loetzsch, K. *Kunstst Ger Plast* v 78 n 2 Feb 1988 p 21-24.

**083278 CRITIQUE ON STABILIZATION TECHNOLOGY IN POLYOLEFINS.** Unstabilized polyolefins are prone to several degradation reactions during the different stages of compounding/processing/fabrication, with catastrophic consequences on product stability and in-service performance. The level of protection afforded by a stabilizer system against the deleterious effects of mechanical, thermal, thermo- and photooxidative degradation reactions is governed by several factors which include both physical and chemical characteristics of the substrate and stabilizer, the environment, and the applica-

tion of stress. In considering the practical aspects for the selection of a stabilizer system, due regards must be given to the structural nonhomogeneity of polyolefins, and to stabilizer substantivity and stability as well as its intrinsic activity. The stabilizer function is examined here in the light of current understanding of the behavior of functions of antioxidants and stabilizers. Several examples are included to reinforce the mechanistic aspects of different classes of antioxidants. (Edited author abstract) 14 refs.

**083279 INTERACTION OF  $\text{Cu}^{2+}$  WITH ETHANEDIOIC ACID BIS-HYDRAZIDES.** The chelating properties of oxalyl dihydrazide and a series of ethanedioic acid bis-hydrazides with  $\text{Cu}^{2+}$  in solution have been investigated by UV absorption and fluorescence quenching measurements. The UV absorption data indicate 1:1 complexation with equilibrium constants in the range  $K_C = 0.57\text{--}2.1 \times 10^6 \text{ mol}^{-1}$  for the bis-hydrazides and  $K_C = 8 \times 10^4 \text{ mol}^{-1}$  for oxalyl dihydrazide. The fluorescence quenching data for the 1-pyrenyl derivative confirm  $\text{Cu}^{2+}$  complexation. The relevance of these finds to the role of ethanedioic acid bis-hydrazides as  $\text{Cu}^{2+}$  chelating agents in polymers is discussed. (Author abstract). 28 Refs.

**Structure** See Also COMPOSITE MATERIALS—Oxidation.

**083280 EFFECT OF CRYSTALLIZATION CONDITIONS ON STRUCTURE AND DIELECTRIC PROPERTIES OF POLYOLEFINS.** An increase in the cooling rate of a melt of PE and PP leads to a substantial drop in the  $T_g$ , degree of crystallinity, inductive capacity and in the tangent of the angle of dielectric losses at low frequencies. The non-equilibrated structure of PE and PP films prepared by quenching the melt at  $77^\circ\text{K}$ , is transferred to an equilibrium state after heating up to room temperature. This transition is accompanied by an increase in the tangent of the angle of dielectric loss as  $T_g$  decreases due to a relaxation of internal stresses and an increase in the degree of crystallinity. (Author abstract) 15 refs.

## Synthesis

**083281 LIVING CARBOCATIONIC POLYMERIZATION: XV. TELECHELIC POLYISOBUTYLENES BY THE  $\text{CH}_3\text{O}(\text{CH}_2)_2\text{C-pC}_6\text{H}_4\text{C}(\text{CH}_3)_2\text{OCH}_3 \cdot \text{TiCl}_4$  INITIATING SYSTEM.** The synthesis of symmetrical linear telechelic polyisobutylenes (PIB) carrying  $-\text{CH}_2\text{C}(\text{CH}_3)_2\text{Cl}$  end groups has been accomplished by living isobutylene (IB) polymerization using the  $\text{CH}_3\text{O}(\text{CH}_2)_2\text{C-pC}_6\text{H}_4\text{C}(\text{CH}_3)_2\text{OCH}_3 \cdot \text{TiCl}_4$  initiating system in  $\text{CH}_2\text{Cl}/n\text{-C}_6\text{H}_{14}$  (40/60 v/v) at  $-80^\circ\text{C}$ . The living nature of the polymerization was demonstrated by linear  $M_n$  versus amount of PIB formed plots starting at the origin. Polymers with up to  $M_n = 126,000$  and  $M_w/M_n = 1.1$  have been prepared. The effect of temperature on the polymer structure has been investigated. Undesirable indanyl end groups which form in polymerizations even at  $-80^\circ\text{C}$  can be eliminated by preparing the initiating di-tert-ether  $\cdot \text{TiCl}_4$  complex in the presence of monomer. (Edited author abstract) 14 refs.

**083282 FUNCTIONAL POLYMERS LI: CHARACTERIZATION AND PROPERTY ANALYSIS OF  $\omega$ -FUNCTIONALLY SUBSTITUTED POLYOLEFINS: NOVEL POLYOLEFIN IONOMERS.** Homopolymers of 2,6-dimethylphenyl 10-undecenoate and copolymers of 2,6-dimethylphenyl 10-undecenoate with  $\alpha$ -olefins, prepared by coordination initiators using aluminum activated titanium trichloride, and the corresponding sodium carboxylate and carboxylic acid derivatives have been characterized. IR and NMR investigations gave the normal spectral characteristics typical for ester-substituted polyolefins and their derivatives. The thermal behavior of the polymeric esters, investigated by differential scanning calorimetry, showed glass transitions characteristic of poly( $\alpha$ -olefins). Polymeric acids and salts presented quite different behavior. (Edited author abstract) 21 refs.

## Thermal Properties

**083283 THERMAL PROPERTIES OF BINARY POLYOLEFIN BLENDS.** The thermal properties of binary polyolefin blends (LDPE/HDPE, LDPE/PP, HDPE/PP) were examined by differential scanning calorimetry. The addition of a second polymer lowers the melting temperature although the melting temperature depression is not a defined function of the blend composition. DSC curves show two melting and two crystallization temperatures. The difference between crystallization temperatures for blends containing PP is smaller than the difference between melting temperatures. The enthalpies of fusion are nearly monotonic functions of blend composition. (Author abstract). 6 Refs.

## POLYPEPTIDES

### Adsorption

**083284 FORCES BETWEEN MODEL POLYPEPTIDES AND PROTEINS ADSORBED ON MICA SURFACES.** The forces of interaction between proteins and model polypeptides adsorbed onto mica have been measured as a function of the distance of separation between the mica surfaces in aqueous solution. Results were obtained for the basic polypeptide, poly-L-lysine, of molecular weight 4,000 and 75,000, cytochrome c, concanavalin A and myelin basic protein. For cytochrome c, no interaction between the adsorbed protein layers was noted until the surfaces were separated by 12.5 nm whereupon an attraction was measured, indicating that the negatively charged mica had been neutralized by adsorption of the positively charged cytochrome c. (Edited author abstract) 32 refs.

Afshar-Rad, T. (Imperial Coll, London, Engl); Bailey, A.I.; Luckham, P.F. *Colloids Surf* v 31 May 1988, Polym in Colloid Syst: Adsorpt, Stab and Flow, Proc of an Int Conf, Veldhoven, Neth, Sep 7-9 1987 p 125-146.

### Biodegradation

**083285 PREPARATION AND PROPERTIES OF CHARGED COPOLYPEPTIDE MEMBRANES AS BIODEGRADABLE MATERIALS.** Three component random copolypeptides consisting of N-hydroxyalkyl L-glutamine, L-glutamic acid, L-lysine were prepared by carrying out aminolysis reactions with aminoalcohols, such as 3-amino-1-propanol (P) or 5-amino-1-pentanol (Pe), followed by crosslinking reaction with octamethylenediamine (OMDA) on starting polymer membranes consisting of  $\gamma$ -methyl-L-glutamate (M), L-glutamic acid

(B), and L-lysine (K). The effective crosslink density was shown to be proportional to the content of the crosslinker (OMDA) in the reaction mixture. Biodegradation of the samples in vitro by pronase E and pepsin indicated that the degradation could be regarded as a bulk rather than a surface phenomenon. The rate of degradation was also highly dependent on the degree of swelling of membranes, as well as on the hydrophobicity and effective charge density of side chains of the samples. (Edited author abstract) 22 refs.

Hayashi, Toshio (Kyoto Univ, Kyoto, Jpn); Nakanishi, Eiji; Nakajima, Akio. *Polym J* v 19 n 9 1987 p 1025-1032.

**083286 ENZYMATIC DEGRADATION OF SEQUENTIAL POLYMERS CONTAINING A TRIPEPTIDE SEQUENCE L-ALANINE-L-LEUCINE- $\gamma$ -ETHYL L-GLUTAMATE AND AN  $\alpha$ -HYDROXY ACID L-LACTIC ACID OR  $\alpha$ -AMINO ACID L-ALANINE.** A study was made with the objective to obtain sequential polymers having good biocompatibility and biodegradability. For this purpose, a sequential polydepeptide of three  $\alpha$ -amino acids such as L-alanine (Ala), L-leucine (Leu), and  $\gamma$ -ethyl L-glutamate (Glu(OEt)) and one  $\alpha$ -hydroxy acid such as L-lactic acid (Lac), poly(Ala-Leu-Glu(OEt)-Lac), was synthesized by polycondensation of tetradepsipeptide active ester. The sequential polymers were then degraded by three kinds of enzymes, lipase as an esterase, papain as an endopeptidase, in order to learn the differences in enzymatic degradation between two polymers. The in vivo degradation was attempted by implanting the polymers subcutaneously in the back of rats, for the comparison with the above enzymatic degradation. 7 refs.

### Crystallization

**083287 STUDIES ON SIDECCHAIN CRYSTALLIZATION OF POLY( $\gamma$ -N-ALKYL L-GLUTAMATE).** The sidechain crystallization of poly( $\gamma$ -n-alkyl L-glutamate)s (PALG) with n=10 to 18 has been studied. X-ray diffraction analysis indicates that the crystalline structures are triclinic for polymers with n  $\geq$  14. Crystalline spacings were found to be nearly the same for all the samples investigated. A small odd-even oscillation with n was observed in thermodynamics quantities such as melting temperature, and the associated enthalpy and entropy changes. The observed enthalpy  $\Delta H_f$  and entropy of melting  $\Delta S_f$  are compared with those reported for the other polymer systems including poly(alkyl acrylate)s and poly(alkyl maleimide)s. It is concluded that the disorientation of sidechains is the major contributor to observed values of  $\Delta H_f$  and  $\Delta S_f$ . (Edited author abstract) In Japanese. 13 refs.

### Elasticity

**083288 THEORETICAL STRESS-STRAIN ISOTHERMS FOR ELASTIN MODEL NETWORKS.** A theoretical analysis was carried out for polypeptides composed exclusively of one of the three highly conserved repeat sequences present in the biolastomer elastin. Conformational energy maps of the relevant amino acids were generated and a standard matrix method used. Various levels of intramolecular hydrogen bonding were studied. Monte Carlo techniques were used to evaluate the distribution functions of the end-to-end distance vector, from which the modulus as a function of elongation was calculated. With minor exception, the resulting stress-strain isotherms for chains having degree of polymerization 5 and 10 showed little deviation from Gaussian

behavior for elongation ratios up to 2. (Edited author abstract) 34 refs.

**083289 TEMPERATURE-DEPENDENT  $\beta$  STRUCTURE-RANDOM COIL CONVERSION OF POLY(S-CARBOXYMETHYL-L-CYSTEINE).** The effect of temperature on the  $\beta$  structure-random coil conversion of poly(S-carboxymethyl-L-cysteine) has been examined on the following well defined systems: folded-chain  $\beta$  and extended-chain  $\beta$  structures. The conversion was reversible but the rate of  $\beta$  formation was very slow for both types of  $\beta$  structure. For folded-chain  $\beta$  structure, the rate of  $\beta$  formation decreased with decreasing polymer concentration. Optical activity associated with the  $n\pi^*$  transition of peptide chromophore scarcely changed with the temperature-induced  $\beta$ -coil conversion. (Author abstract) 31 refs.

Fukada, Kazuhiro (Nagoya Univ, Nagoya, Jpn); Maeda, Hiroshi; Ikeda, Shoichi. *Polymer* v 28 n 11 Oct 1987 p 1887-1892.

**083290 POLYMERIZATION AND CONFORMATIONAL STUDIES OF POLY(TRANS-3-ETHYL-D AND L-PROLINE).** Poly (L-trans-3-ethylproline), L-PT3EP, and poly(D-trans-3-ethylproline), D-PT3EP, were prepared by ring opening polymerization of the corresponding N-carboxyanhydrides (NCA) using triethylamine as an initiator. Using circular dichroism spectroscopy, it was shown that the incorporation of an ethyl group at the 3 position of the pyrrolidine ring caused a noticeable change in the conformational behavior of the polymer in solution. The ethyl group limited to some extent rotation of the polymer chain around the C $\alpha$ -CO bond and prevented the mutarotation between the two forms found in poly-L-proline polymers. (Author abstract) 18 refs.

Tiba, Omar (Univ of Michigan, Ann Arbor, MI, USA); Overberger, C.G. *J Polym Sci Part A* v 25 n 11 Nov 1987 p 2941-2952.

**083291 MIXED MONOLAYERS OF POLYPEPTIDES.** Mixed monolayers of two polypeptides, poly- $\gamma$ -methyl-L-glutamate and poly-L-alanine, in the same  $\alpha$ -helix surface conformation, were studied at the water/air interface. From a comparison of the experimental  $\pi$ -A isotherms with Huggins' theory and from the examination of the MIR spectra for the two components and their mixtures, it was possible to deduce that poly- $\gamma$ -methyl-L-glutamate and poly-L-alanine were totally miscible at the surface with prevalently attractive interactions and that the mixtures maintained the conformation of the two components. The low values of the interaction parameters, deduced by applying Joos' theory to the collapse pressures of the mixtures, demonstrated that the interactions were prevalently hydrophobic. (Author abstract) 16 refs.

### Processing

**083292 POLYMERIC PHOSPHOLIPID ANALOGS. XXII. A SYNTHETIC POLYPEPTIDE WITH PHOSPHOLIPID ANALOGS.** The authors prepared a synthetic polypeptide containing phospholipid analogs in the side chain. It is shown that in the IR spectrum of the reaction product, new absorption bands due to the stretching vibration of the hydroxy group and to the methylene groups appeared at 3250 and 2930 cm $^{-1}$ , respectively. The polymer was soluble in DMF, but almost insoluble in chloroform and acetone, and it exhibited a liquid crystalline phase from room temperature to 170°C. The same polymer was insoluble even in

DMF when dried completely in vacuo. 13 refs.

## Production

**083293 PHOTOINDUCED CONFORMATIONAL TRANSITION OF POLYPEPTIDES CONTAINING AZOBENZENESULFONATE IN THE SIDE CHAINS.** Photoresponsive polypeptides, poly(L-glutamic acids) containing 1.9, 9.3 and 46.3 mol% azobenzenesulfonate moieties in the side chains (azo-S-PGA), have been prepared by condensation reaction of poly(L-glutamic acid) (PGA,  $M_v = 1.19 \times 10^5$ ) with 4-amino-1,1'-azobenzene-4'-sulfonic acid sodium salt in dimethylformamide solution and the photoresponsive behavior of the copolypeptides obtained was investigated. The dark-adapted azo-S-PGAs containing 1.9 and 9.3 mol% azobenzenesulfonate (azo-S) moieties showed a pH-dependent  $\alpha$ -helix to coil transition; however, the copolypeptide containing 46.3 mol% azobenzenesulfonate moieties was in the random coil conformation at any pH. (Edited author abstract) 25 refs.

Sato, Morimasa (Nagoya Inst of Technology, Nagoya, Jpn); Kinoshita, Takatoshi; Takizawa, Akira; Tsujita, Yoshiharu. *Macromolecules* v 21 n 6 Jun 1988 p 1612-1616.

## Research

**083294 THERMOTROPIC POLYPEPTIDES. 5. TEMPERATURE DEPENDENCE OF CHOLESTERIC PITCHES EXHIBITING A CHOLESTERIC SENSE INVERSION.** The cholesteric pitches were determined for the thermotropic cholesteric mesophases of poly(( $\gamma$ -benzyl L-glutamate)-co-( $\gamma$ -dodecyl L-glutamate)) with the dodecyl content of 58% in the wide temperature range from 100 to 250°C. The pitches in an initial temperature range 100-130°C are comparable to the wavelength of visible color and increase with rising temperature. After the pitches diverge at 195°C, they decrease as temperature is raised further. In contrast to this anomalous behaviour of pitches, the reciprocal pitches (measuring the twisting angles) vary smoothly with the temperature along a curve. The curve exhibits a remarkable variation of twisting angle at lower temperature and seems to approach a constant value at higher temperature, passing through zero at 195°C. (Edited author abstract) 22 refs.

Watanabe, Junji (Tokyo Inst of Technology, Tokyo, Jpn); Nagase, Tatsuya. *Macromolecules* v 21 n 1 Jan 1988 p 171-175.

## Solutions

**083295 ESR STUDY OF GEL-SOL TRANSITIONS OF POLY(L-LEUCINE)-BENZENE SOLUTION BY SPIN-LABELING TECHNIQUE.** An ESR study of poly(L-leucine)-benzene solution ranging in concentration from 0.1 to 6.0 wt% was carried out by spin-labeling technique in the temperature range from room temperature to 90°C. The ESR spectra of these samples showed that radicals undergo restricted motion in this temperature range. It was found that the line separation of the ESR spectrum changes remarkably around 50 and 70°C. These temperatures correspond to the temperatures of the gel-sol transitions, suggesting the existence of two kinds of gel states in these samples. Heats of dissociation of these gels were estimated at 160 and 42 kcal for a mol of network junctions, respectively, for the poly(L-leucine) with a number-average molecular weight of  $10^4$ . (Author abstract) 11 refs

Anada, Yuichi (Hokkaido Univ, Sapporo, Jpn); Tsutsumi, Akihiro; Hideshima, Teruo; Hikichi, Kunio; Yokoi, Jun; Tokura, Seiichi. *Polym J* v 19 n 8 1987 p 939-943.

**083296 REVERSING-PULSE ELECTRIC BIREFRINGENCE OF POLY( $\gamma$ -BENZYL L-GLUTAMATE) IV. ELECTRIC, OPTICAL, AND HYDRODY-**

**NAMIC PROPERTIES IN HELIX-FORMING SOLVENTS AS EVALUATED FROM FIELD-ON AND FIELD-OFF PROCESSES.** Reversing-pulse electric birefringence (RPEB) of poly( $\gamma$ -benzyl L-glutamate), [Glu(OBzl)]<sub>n</sub>, with a weight-average molecular weight of  $1.71 \times 10^5$  was measured at 20°C and at 535 nm in four helix-forming solvents: 2-chloroethanol, cyclohexanone, pyridine, in which [Glu(OBzl)]<sub>n</sub> is dissolved molecularly, and chloroform in which it is aggregated. A standard analytical procedure is given for the RPEB signal which represents the field-on and field-off processes. The steady-state birefringence of [Glu(OBzl)]<sub>n</sub> was measured over a wide field strength range up to ca.  $20 \text{ kV cm}^{-1}$ . The Kerr law was obeyed at low fields, while a saturating trend was observed at higher fields. (Edited author abstract) 42 refs.

## Spectroscopic Analysis

**083297 ELECTRON SPECTROSCOPY FOR CHEMICAL ANALYSIS STUDIES ON POLYPEPTIDE SURFACE.** The outer-most surface characteristic of poly( $\gamma$ -benzyl L-glutamate) (PBLG) and poly( $\epsilon$ -N-benzoyloxycarbonyl L-lysine) (PBCL) were investigated by electron spectroscopy for chemical analysis (ESCA). These homopolypeptides exist in the  $\alpha$ -helical conformation in the solid state. The ESCA measurements showed the ratios (O/C) of atomic concentrations of both polypeptides are in accord with the bulk values for grazing angles from 45° to 60°. As the result of the evaluation of effective sampling depth estimated from the electron mean free path, we obtained  $d = 16.3$  angstrom to 19.9 angstrom for PBLG and  $d = 16.6$  angstrom to 20.4 angstrom for PBCL in the same grazing range. The diameters of the cross-section,  $\alpha$ , of PBL and PBCL helical rods have been reported as  $a = 15.0$  angstrom and 18.0 angstrom, respectively. (Edited author abstract) 22 Refs. In Japanese.

## Stability

**083298 DIMENSIONAL CHANGES OF POLYPEPTIDES IN THE HELIX-SENSE INVERSION REGION.** Dimensional changes of polypeptides in the helix-sense inversion region are analyzed by a theory based on the three-state, nearest-neighbor interaction model. Each peptide residue in a chain is assumed to take on right- and left-handed  $\alpha$ -helical states as well as a random coil state, and the helix stabilization effect due to hydrogen-bond interactions is taken into account. Such interactions between four consecutive residues have explicitly been discussed in a  $9 \times 9$  statistical-weight matrix in a previous theory, while in the present model we simplify this matrix into the form of a  $3 \times 3$  matrix by considering the interactions only between two consecutive residues. Theoretical transition curves illustrating the general characteristics of the sense inversion phenomena suggest a method for evaluating the transition parameters. (Edited author abstract) 23 refs.

## Synthesis

**083299 N-CARBOXYANHYDRIDES.** According to the definition in the field of polymer chemistry, an  $\alpha$ -amino acid is a monomer of the A-B type, giving polypeptides by polycondensation. However, activation of the amino group or carboxyl group of the amino acid is indispensable if linear high-molecular-weight polypeptides are to be obtained by the polycondensation of  $\alpha$ -amino acids. A typical example of carboxyl group activation is the N-carboxyanhydride (NCA) method, described in this paper. Attention is mainly confined to a review of papers

about the reactions and polymerization of NCAs published since 1965. 269 refs.

**083301 SYNTHESIS, SEPARATION, AND RESOLUTION OF cis- AND trans-3-ETHYLPROLINE.** The synthesis, separation, and optical resolution of cis- and trans-3-ethylproline are described. Two different approaches were employed: The Michael addition reaction of 2-pentenal with diethyl-N-carbobenzoyloxycarbonylmalonate gave the intermediate of 3-ethyl-5-hydroxy-N-benzyl-oxypyrrolidine. Hydrogenolysis of this intermediate followed by acid hydrolysis gave a mixture of cis- and trans-3-ethylproline. The Michael condensation of diethyl acetamidomalonic acid with 2-pentenoic acid ethyl ether produced the intermediate 5,5-bis(ethoxycarbonyl)-4-ethylpyrrolidine. The absolute configurations of the optically active isomers were determined by circular dichroism spectroscopy. (Edited author abstract) 52 refs.

## Synthesis

**083306 THEORETICAL AND EXPERIMENTAL CONSIDERATIONS ON POLYDIHALOPHENYLENE OXIDE(S).** The decomposition of copper(II) trihalophenoxides in acetonitrile yields poly(dihalophenylene oxide)s. A  $^1\text{H}$  NMR study has shown that a bromine atom in the 4-position of the trihalophenoxides results in polymers having higher linearity. Various dynamic and static methods, within the framework of Huckel molecular orbital theory, have been used to explain the product distribution. (Author abstract) 14 refs.

**083307 INFLUENCE OF EXPERIMENTAL CONDITIONS ON THE CHEMILUMINESCENCE FROM POLYPROPYLENE AND ABS DURING OXIDATION.** In this report we present results obtained with polypropylene (PP) and acrylonitrile-butadiene-styrene (ABS) films concerning the effect of experimental conditions on these films. They show that the prior history and shape of the sample have a significant influence on the oxidation parameters evaluated by means of chemiluminescence. Powders or very thin films have to be analyzed if one wishes to avoid complications associated with diffusion-controlled oxidation. 11 refs.

**083308 THERMOFORMING OF ORDERED POLYPROPYLENES.** Uniaxial molecular ordering of polyolefin billets by a process of roll-drawing produces clear, transparent sheets having greatly increased strength and modulus in the draw direction whereas the strength and modulus in the transverse direction remain essentially unaltered. Such sheets may be laminated together by means of ultrasonic welding, electromagnetic induction heating or simple pressure lamination using adhesive tie layers to produce multiply laminates with controlled biaxial properties. These self-reinforced laminates have mechanical properties which compare favorably with advanced aramid or carbon fiber composites. Conventional thermoforming techniques may be employed to

convert these highly ordered sheets into shaped products having potential commercial value. In these investigations examples are presented to illustrate the method of laminating and thermoforming of ordered polypropylene sheets. (Edited author abstract) 6 refs.

## Adhesion

**083309 ADHESION OF MOLDED POLYPROPYLENE USING POLYPROPYLENE GELS.** It is well known that securing good adhesion between polypropylene plate and other material, especially between two polypropylene plates, is difficult because of polypropylene's nonpolarity and high crystallinity. To increase the strength of the adhesion of a material to a polypropylene molding, it is necessary to activate the polypropylene surface by various methods. In this work, results of a study of the adhesion between polypropylene plates using polypropylene gels are reported. 10 refs.

## Aging

See Also PLASTICS FILMS—Thermal Effects.

**083310 AGING PHENOMENA IN ISOTACTIC POLYPROPYLENE DRAWN AT DIFFERENT TEMPERATURES.** Fibers of isotactic polypropylene drawn at different temperatures show aging phenomena after drawing. In particular a modulus stiffening is observed at room temperature where the modulus increases with the aging time. In the same time scale the birefringence is constant, while drastic effects on the transport properties are observed. The aging phenomenon can be explained in terms of two mechanisms: a secondary crystallization and/or a densification of the amorphous component. (Author abstract). 29 Refs.

## Analysis

**083311 APPLICATION OF THERMAL ANALYSIS FOR INVESTIGATIONS OF POLYMER POWDERS FOR COATINGS.** Polypropylene coatings obtained by the fluidized bed method were investigated. It was proved that the application of thermal analysis methods for their characterization gave many useful data, as a consequence of the similar conditions of thermal measurements and plastics powder processing. Significant correlations were found between the thermal properties and the standard coating properties. (Author abstract) 3 refs.

## Antioxidants

**083312 GAMMA-IRRADIATION OF FOOD CONTACT PLASTICS: THE RAPID DESTRUCTION OF AN ARYLPHOSPHITE ANTIOXIDANT IN POLYPROPYLENE.** In a recent communication, preliminary details were reported of a study of the effects of progressive doses of gamma-irradiation on the extractable levels of various hindered phenol antioxidants present in a range of food contact polymers. Now, a preliminary report is presented of a similar study of the effects of gamma-irradiation on polypropylene containing an arylphosphite antioxidant, Irgafos 168, either as the sole antioxidant present or as a component of synergistic mixture with the hindered phenolic antioxidant Irganox 1010. It is clear that Irgafos 168 is destroyed far more rapidly than hindered phenol antioxidants on irradiation, little remaining after a 10 kGy exposure. The rate of destruction would seem to be even greater in the presence of the hindered phenol antioxidant Irganox 1010. How-

ever, the latter suffers degradation at a very similar rate to that observed previously. 7 refs.

**083313 ANTIOXIDATIVE EFFICIENCY OF SUBSTITUTED N-PHENYL N-PYRAZOLYL-3, N-PHENYL N-BENZIMIDAZOLYL-2 AND N-BENZTHIAZOLYL-2 N-BENZIMIDAZOLYL-2 AMINES IN THE THERMOOXIDATION OF POLYPROPYLENE.** The antioxidative efficiency of three different series of nitrogen containing compounds derived from N-phenyl N-(1,5-diphenylpyrazolyl-3), N-phenyl N-benzimidazolyl-2 and N-benzthiazolyl-2 N-benzimidazolyl-2 amines in the thermal oxidation of polypropylene were compared on the bases of the results of chemiluminescence, dynamic thermogravimetry and differential scanning calorimetry. The effect of substituents on phenyl rings and on the 1-nitrogen of benzimidazol was examined with respect to the antioxidative behavior of the compounds. Bad dispersion of the additive and its volatility seems to have a large effect, in some cases, on the results of antioxidation tests. (Author abstract). 10 Refs.

**083314 INFLUENCE OF METAL IONS ON ANTI-OXIDANT BEHAVIOUR IN POLYPROPYLENE.** The effect of Cr(III), Fe(III) and Cu(II) ions, at trace levels, on the effectiveness of four commercial antioxidant systems, viz. Topanol, Santowhite, Hostanox 03 and Irganox 1425 in polypropylene (PP) films is examined using infra-red and second-order derivative uv spectroscopy. The results show that at these levels the metal ions have a minor effect on the unstabilised polymer. However, the ions can have a beneficial or adverse effect on antioxidant activity, particularly under oven ageing conditions. The observed effect depends on the metal/antioxidant system, and is attributed to an indirect interaction between the components which can delay or accelerate antioxidant decomposition in the polymer. An exception to this behaviour is the metal complex Irganox 1425, which interacts strongly with copper ions in the polymer matrix. The antioxidant is partially transformed by copper ions during the compression moulding stage. The beneficial effect present in some cases is in direct contrast with what has generally been observed in studies using unstabilised polymers. (Author abstract) 16 refs.

Chirinos-Padron, Alfonso J. (Venezolano de Investigaciones Cientificas, Caracas, Venez); Hernandez, Petra H.; Suarez, Felipe A. *Polym Degradation Stab* v 20 n 3-4 1988, Polym Addit in Stab: Perform and Mech, Birmingham, Engl, Sep 2-4 1987 p 237-255.

**083315 ANTIOXIDANT CROSSOVER EFFECT IN OVEN AGEING OF POLYPROPYLENE.** Thermal oxidative stabilities of polypropylene formulations are frequently assessed by ageing samples in circulating-air ovens. A 150°C test temperature is almost an accepted standard throughout the polymer industry although it often bears little relation to the actual service temperatures seen during the life of the polypropylene which are frequently below 100°C. Phenolic antioxidants are necessary for the extended service life of polypropylene. When the antioxidants are compared over a range of evaluation temperatures, their relative performance can change quite markedly. As evaluation temperatures are decreased and approach actual use temperature, the chemical kinetics of stabilization and the influencing physical characteristics of the antioxidant appear to change causing a reversal in the relative effectiveness between two high molecular weight antioxidants. This has been defined as the 'crossover

effect'. This understanding should allow for improved predictions of polymer service life. (Author abstract) 7 refs.

**083316 POLYOLEFIN BLENDS: 2. EFFECT OF EPR COMPOSITION ON STRUCTURE, MORPHOLOGY AND MECHANICAL PROPERTIES OF IPP/EPR ALLOYS.** The morphology, thermal behavior, tensile and impact properties of sheet specimens of isotactic polypropylene (iPP) blended with ethylene-propylene copolymers (EPR) containing different amounts of polypropylene or polyethylene blocks and various extents of crystallinity were investigated by means of optical and scanning electron microscopy, differential scanning calorimetry, wide-angle X-ray diffractometry, impact and tensile mechanical tests. The experimental results showed that copolymers containing polypropylene or polyethylene blocks could act as nucleating agents for iPP spherulites. It was found that the mode and state of dispersion of the EPR copolymers, as well as the thermal and mechanical behavior of the blends, depended upon the composition of the copolymer used in the blends for given crystallization conditions. **Chemical Reactions** See Also CHEMICAL REACTIONS—Reaction Kinetics.

**083317 INFLUENCE OF THE CONDITIONS UNDER WHICH PHOSPHINATED POLYPROPYLENE SUPPORTS ARE PREPARED ON THE PERFORMANCE OF SUPPORTED RHODIUM(I) OLEFIN HYDROFORMYLATION CATALYSTS.** The detailed structure of the support can play a major part in influencing the specificity and selectivity of reactions catalyzed by polymer-supported catalysts. Accordingly we have examined carefully the influence of the conditions under which phosphinated polymer supports are prepared when p-styryldiphenylphosphine is grafted onto polypropylene in the presence of gamma-radiation. A number of different reactions take place simultaneously. Their relative rates can be altered by changing the solvent in which the irradiation is performed; changing their rates alters the nature and detailed structure of the phosphinated polypropylene supports. A series of phosphinated polypropylene supports prepared in benzene, tetrahydrofuran and dimethylsulphoxide were used to support rhodium(I). The activity, specificity and selectivity of these catalysts in olefin hydroformylation was studied. It was found possible to prepare polymer-supported catalysts that were more active than their homogeneous counterparts and which retained the high selectivity for straight-chain as opposed to branched aldehyde formation, as well as high specificity for hydroformylation as opposed to olefin isomerisation. **083318 QUANTITATIVE SIZE EXCLUSION CHROMATOGRAPHY OF POLYPROPYLENE I:**

**METHOD DEVELOPMENT.** Polypropylene was analyzed by size exclusion chromatography (SEC) at 145°C using a single-differential refractometer detector. The objective was to provide data for characterization of polypropylene degradation during a reactive extrusion process. Two antioxidants were tested for their ability to prevent thermal degradation of the polypropylene during sample preparation. The use of 0.20 wt% of (I) was effective during the 36-48 h required to completely dissolve the samples in trichlorobenzene for SEC analysis. 'Reshaping' of the chromatograms by resolution correction demonstrated that, while the molecular weight averages were changed by 8% because of axial dispersion, most of the individual heights of the distributions were changed by less than 2%. (Edited author abstract) 23 refs.

Lew, R. (Univ of Toronto, Toronto, Ont, Can); Suwanda, D.; Balke, S.T. *J Appl Polym Sci* v 35 n 4 Mar 1988 p 1049-1063.

**083319 QUANTITATIVE SIZE EXCLUSION CHROMATOGRAPHY OF POLYPROPYLENE II: ANALYSIS SYSTEMS.** Quantitative size exclusion chromatography (SEC) was considered a system with the following components; sample preparation, fractionation, detection, calibration, and resolution correction. Four systems were evaluated: I was 3 columns with 'conventional single detector interpretation'; II was four columns with concentration correction and detector assessment; III was concentration correction applied to the data of I; IV was two development 'mixed bed' columns. Analysis of polystyrene standards included calculation of their molecular weight averages and use of the Glockner T measure of resolution was well as 'specific resolution index'. Systems I and III provided the best high molecular weight results. (Edited author abstract) 15 refs.

## Coloring

**083320 THERMOCHROMISM OF POLYPROPYLENE GELS.** It is found that polypropylene gels in some solvents of benzene-derivatives show a striking change of color. The color changes from blue to yellow as the temperature rises from the melting point of the solvent to around 70-80°C. The apparent characteristic of the phenomenon resembles the thermochromism of cholesteric liquid crystals although polypropylene itself is colorless and has no asymmetric carbons in the molecules. Polypropylene flakes swelled in these solvents also show similar thermochromism. (Author abstract) 30 refs.

## Compounding

**083321 RECENT DEVELOPMENTS IN POLYPROPYLENE COMPOUNDING.** The market for polypropylene compounds is enjoying rapid expansion. Not only is the tonnage increasing but also the range of materials available. While talc fillers and elastomer rubbers such as EPR continue to be the main modifiers, growth is being seen in other compounds as well. The continued demand for polypropylene compounds in such applications as automotive parts, appliances, furniture and construction confirms their position among the engineering plastics group, and as the quality of products available improves so is their permanence assured. This paper will review these developments, paying particular attention to recent polymer and filler modifications.

Ellis, Patrick (Neste Polypropylene NV, Beringen, Belg). *Kem Kem* v 15 n 2 1988 p 127-129.

## Crazing

**083322 FORMATION OF CRAZES IN ISOTACTIC POLYPROPYLENE AND ACCOMPANYING CHANGES OF ENERGY.** Formation and growth of crazes in isotactic polypropylene with c-texture crystallites

arranged in lamellae oriented perpendicularly with respect to the texture axis have been investigated by small-angle X-ray scattering and calorimetry. Deformation of polypropylene along the texture axis leads to the formation of a great number of crazes localized in the interlamellar volume of the crystalline polymer. During the period of craze growth the mean diameter of fibrils connecting the craze walls remains practically constant while the specific surface area increases with deformation. (Edited author abstract) 8 refs.

## Crystallization

**083323 NUCLEATING ACTIVITY OF METAL SALTS OF BENZOIC ACID IN POLYPROPYLENE.** The nucleating activity of metal salts of benzoic acid in polypropylene (PP) was investigated. A nucleator of different crystallinity, aluminum benzoate hydroxide, was used. The crystal of this nucleator had a leaf-like shape, about 50 nm across. The nucleating activity of the crystal which had a layer structure was rapidly decreased when the structure was destroyed. The microstructure of PP determined by electromicroscopic observations, varied with the crystallinity of the nucleator. This nucleating activity also showed a temperature dependence. These results indicate that the nucleating activity of aluminum benzoate hydroxide is attributable to an absorption of PP on the layer of the crystal under supercooling. (Edited author abstract) In Japanese. 13 refs.

Ikeda, Kiyoshi (Industrial Research Inst of Hyogo Prefecture, Kobe, Jpn). *Kobunshi Ronbunshu* v 44 n 7 1987 p 539-543.

**083324 STRUCTURAL 'MEMORY' EFFECT IN ISOTACTIC POLYPROPYLENE MELTS.** An isotactic-polypropylene oriented sheet with the predominant  $\beta$ -crystal form which was induced by the elongational flow of polymer melts was prepared. The effects on  $\beta$ -form formation of the temperature at which the sheet was melted and of the time spent at melting temperature before crystallization have been studied by using DSC of the melting behavior of the polymer isothermally crystallized from the melt. The results show that the active crystallization center of  $\beta$ -form has a higher thermal stability beyond the melting point and that the melt does not lose its structural 'memory' during annealing for 10 min at 180°C, but this is lost during annealing for 1 min at 230-240°C. (Author abstract) 14 refs. In Japanese.

Itoyama, Kuniyoshi (Toray Industries Inc, Sonoyama, Jpn). *Kobunshi Ronbunshu* v 44 n 5 1987 p 405-408.

**083325 FAST DSC APPLIED TO THE CRYSTALLIZATION OF POLYPROPYLENE.** In an effort to find the limit of crystallization of polypropylene, a series of quantitative and semiquantitative DSC experiments at rates up to 10,000 deg/min are described. Even at these fast rates polypropylene crystallized on cooling between 350±15 K and 280±6 K. No fully amorphous polypropylene was produced. No initial stage crystallization to the cond state could be proven by quenching after partial crystallization. (Author abstract). 21 Refs.

Wu, Zong Quan (Rensselaer Polytechnic Inst, Troy, NY, USA); Dann, V.L.; Cheng, S.Z.D.; Wunderlich, B. *J Therm Anal* v 34 n 1 Jan-Feb 1988 p 105-114.

## Decomposition

**083326 COMPARISON OF THE KINETICS OF THE DECAY OF PEROXIDE RADICALS IN THE CRYSTALLINE PHASE OF POLYPROPYLENE AND POLY-4-METHYLPENTENE-1.** The kinetics of

the decay of peroxide radicals of polypropylene and poly-4-methylpentene-1 in oxygen and an inert atmosphere has been studied. It is shown that the presence of reactive mobile side groups in poly-4-methylpentene-1 removes the 'conformational prohibition' from the reaction of breakdown of the peroxide macroradical existing in the crystalline phase of polypropylene leading to its death and promotes the averaging of the kinetic non-equivalence of the peroxide macroradicals of the main polymer chain. (Author abstract) 12 refs.

**Deformation** See Also PLASTICS FILMS—Drawing and Stamping.

**083327 MECHANICS OF EQUIBIAXIAL HYDROSTATIC DEFORMATION IN SOLID STATE: ISOTACTIC POLYPROPYLENE.** A simple model describing the process mechanics is presented. The model is verified by direct measurement of compression force versus compressive strain data. This is followed by a comparison of the theory and experiment. 31 refs.

Saraf, Ravi F. (Univ of Massachusetts, Amherst, MA, USA); Porter, Roger S. *J Rheol* v 31 n 1 Jan 1987 p 59-94.

**083328 DILATIONAL DAMAGE ACCUMULATION DURING FATIGUE OF POLYPROPYLENE.** Plastic deformation in spherulitic polypropylene includes a component of dilatational strain. Residual volume changes have been measured as a function of uniaxial strain for tension, compression and cyclic tests. In compression, the volume changes were measured during the test while the specimen was under load and the stress maximum was found to be related to the onset of rapid dilation. The dilation for all modes of mechanical testing was found to be linearly dependent on the tensile component of the strain. Microstructural changes responsible for these observations were examined using transmission electron microscopy of permanganic etched interior surfaces of the deformed specimens. Microcrazes along interlamellar planes were found in all deformed specimens. Fatigue failure in symmetric tension/compression tests occurred by accumulation of crazes, predominantly on the tensile half cycles. (Author abstract) 26 refs.

Zok, F. (Univ of Western Ontario, London, Ont, Can); Shinozaki, D.M. *J Mater Sci* v 22 n 11 Nov 1987 p 3995-4001.

**083329 EFFECT OF ANNEALING ON A HIGHLY DISPERSED POROUS STRUCTURE, FORMED IN ISOTACTIC POLYPROPYLENE UNDER DEFORMATION.** The effect of annealing on the change of microcraze structure formed during deformation of isotactic polypropylene (PP) at 20° has been studied. With annealing in the 20-100° range, the diameter of the fibrils joining the walls of the microcrazes is increased but the volume of micropores is unchanged as the treatment temperature is increased. In the temperature region above 100°, a decrease in the degree of dispersivity of the material of the microcrazes is accompanied by a decrease in the volume of the micropores. It was shown that annealing leads to stabilization of the porous structure, formed by stretching the PP. (Author abstract). 8 Refs.

Yefimov, A.V. (M.V. Lomonosov State Univ, Moscow, USSR); Bulayev, V.M.; Ozerin, A.N.; Rebrov, A.V.; Godovskii, Yu.; Bakyev, N.F. *Polym Sci USSR* v 29 n 5 1987 p 1125-1132.

## Degradation

**083330 COPPER CARBOXYLATE FORMATION IN THE THERMAL OXIDATIVE DEGRADATION OF ATACTIC POLYPROPYLENE ON COPPER OXIDE FILMS.** The thermal oxidation of atactic polypropylene on CuO<sub>0.67</sub> surfaces in air was studied using IR reflection-absorption spectroscopy. Degradative losses of primary, secondary, and tertiary alkyl hydrogens were observed. At 60 and 73°C, carboxylic acids are the primary

degradation products, while at 85 and 100°C, copper carboxylate formation predominates and CuO<sub>0.67</sub> is decomposed. The distinct change in the oxidative mechanisms between 73 and 85°C apparently is related to an irreversible thermal transition in the atactic polypropylene films, which may favor carboxylate production by increasing the permeability of the films to oxygen and water vapor. (Author abstract) 14 refs.

Webb, John D. (Solar Energy Research Inst, Golden, CO, USA); Czanderna, A.W.; Pitts, J.R. *J Polym Sci Part A* v 25 n 12 Dec 1987 p 3395-3403.

**083331 DEGRADATION OF POLYPROPYLENE IN THE PLASTIFYING UNIT OF AN INJECTION Moulding MACHINE.** Degradation phenomena, caused by thermal and/or mechanical stresses, occur in the processing of polypropylene. Insights into the degradation behaviour already gained earlier from extrusion tests are to be checked in a detailed investigation for injection moulding. (Author abstract) 13 refs. In German and English.

Menges, G.; Ries, H.; Linne von Berg, A.; Klee, D. *Kunstst Ger Plast* v 77 n 11 Nov 1987 p 32-34, 1185-1189.

**083332 PRODUCTION OF CONTROLLED-RHEOLOGY POLYPROPYLENE RESINS BY PEROXIDE PROMOTED DEGRADATION DURING EXTRUSION.** Results of experimental and modeling studies of the peroxide promoted degradation of polypropylene (PP) are presented. Experiments were carried out in glass ampoules and in a plasticating extruder. The initiator, 2,5-dimethyl-2,5-bis(tert-butylperoxy)hexane was used as a radical generator. The extruder used had a 38 mm diameter and 24:1 L/D single-screw. In these experiments, the effect of peroxide concentration and screw speed on the molecular weight distribution (MWD) of the polypropylene resin was studied. Samples collected from the experimental runs were analyzed for melt flow index (MFI), flow curve, extrudate swell, and MWD. The measured data are presented and correlations among various parameters are considered. Generally, it can be concluded that controlled-rheology (CR) resins with lower molecular weight, narrower MWD, and reduced viscosity and elasticity, can be produced. A kinetic model for the peroxide initiated degradation of PP is proposed. Simulations based on this model are compared with experimental data for the production of CR resins. Agreement between model predictions and experimental results is quite satisfactory suggesting that this model should find use in commercial practice. (Edited author abstract) 33 refs.

Tzoganakis, C. (McMaster Univ, Hamilton, Ont, Can); Vlachopoulos, J.; Hamielec, A.E. *Polym Eng Sci* v 28 n 3 Mid-Feb 1988 p 170-180.

**083333 FRACTURE MECHANICS APPROACH TO THE EFFECTS OF UV-DEGRADATION ON POLYPROPYLENE.** A fracture mechanics approach to the ultraviolet degradation embrittlement of polypropylene (PP) semi-crystalline homopolymer has been evaluated. The loss in fracture properties results mainly from embrittlement of the surface resulting in surface defects. Degradation depth was measured by Fourier transform infrared (FTIR) spectrometry. Degraded and notched specimens were tested at different deformation velocities in three-point bending. Fracture energies of degraded specimens and specimens notched with a depth equal to that of degradation are compared. Differences are accounted for by different fracture processes which were observed by studying fracture surfaces. (Edited author abstract) 22 refs.

Schoonenberg, G.E. (Technical Univ of Delft, Delft, Neth). *J Mater Sci* v 23 n 5 May 1988 p 1580-1590.

## Dielectric Properties

**083334 EFFECT OF WATER ON DIELECTRIC RELAXATIONS IN THE GLASSY STATES OF POLY(PROPYLENE OXIDE) AND PROPYLENE**

**GLYCOL.** The dielectric permittivity and loss of poly(propylene oxide),  $M_w=425$  and propylene glycol (PG) and their mixtures with water were measured in the temperature range 77-320 K and frequency range  $12.5 \times 10^5$  Hz. PPO-425 has two relaxation processes which appear as  $\beta$ - and  $\alpha$ -peaks, but the  $\beta$ -peak in PG is masked by a large contribution to the loss from the  $\alpha$ -process. Addition of water up to 1.25 wt% changes the temperature or the rate of the  $\alpha$ -process in both PPO-425 and PG, and increases the half-width of the  $\alpha$ -relaxation in PG. Water decreases both the rate and the strength of the  $\beta$ -process in PPO-425. The strength of the  $\beta$ -process increases with increase in the molecular weight of PPO. (Edited author abstract) 12 refs.

Pathmanathan, K. (McMaster Univ, Hamilton, Ont, Can); Johari, G.P. *Polymer* v 29 n 2 Feb 1988 p 303-310.

**083335 AC BREAKDOWN OF MELT-CRYSTALLIZED ISOTACTIC POLYPROPYLENE.** The effect of polymer morphology on the dielectric breakdown of isotactic polypropylene was investigated under the influence of a ramped ac voltage. Samples were prepared by melt-pressing polypropylene beads into plaques and subsequently quenching or isothermally crystallizing these plaques. Some of the quenched samples were annealed at different temperatures to induce further crystallinity. The plaques were then characterized by wide-angle X-ray diffraction, density measurements, and differential scanning calorimetry. The 60 Hz ac breakdown voltages of the samples were determined at 7, 23 and 45°C in a specially designed test cell. There was a lack of any significant effect on the ac breakdown strength of isotactic polypropylene of either the overall crystallinity or the crystallite thickness. It is postulated that the degree of crystallinity would influence the breakdown characteristics only when the amorphous regions constitute a small fraction of the total volume. (Edited author abstract) 26 refs.

Krishnakumar, B. (State Univ of New York at Buffalo, Buffalo, NY, USA); Gupta, R.K.; Forster, E.O.; Laghari, J.R. *J Appl Polym Sci* v 35 n 6 May 5 1988 p 1459-1472.

**083336 DEPENDENCE OF THE ELECTRIC STRENGTH ON THICKNESS AREA AND VOLUME OF POLYPROPYLENE.** A dependence of the electric strength on thickness, area, and volume of dielectric is demonstrated for polypropylene film. It was found that the electric strength of the polymer film decreases with volume. It is shown that the function of electric strength is not simply dependent on the volume as obtained from the theory of extreme values, but that an increase of the volume caused by increasing the thickness of the dielectric is much more significant than the same increase of the dielectric volume caused by an increase in area. The theoretical results presented are in very good agreement with the experimentally obtained values. 4 refs.

**Drawing and Stamping** See Also PLASTICS SHEETS—Thermoforming; POLYETHYLENES—Drawing and Stamping.

**083337 DRAWING THICK SECTION POLYPROPYLENE AT HIGH STRAIN RATES.** Tensile deformation studies are reported for propylene homopolymer specimens up to 4.5 mm thick at strain rates up to  $1.67 \text{ s}^{-1}$  (process conditions pertinent to an industrial solid phase forming process). Simple models of the deformation process are used to predict the axial distribution of stress and strain rate in the neck region and the adiabatic temperature rise in an element passing through this deformation zone. The temperature rise predictions are compared with surface temperature measurements obtained by means of a thermal imaging system. (Author abstract) 16 refs.

**083338 ORIENTING POLYPROPYLENE SHEET BY ROLLING-DRAWING.** Rolling-drawing is a simple, effective method for manufacturing high-strength, high-modulus sheet from polymer billets. Using inexpensive equipment and straightforward controlling techniques, processors can increase the tensile modulus and strength of polypropylene by more than an order of magnitude. Polypropylene sheets 1 to 3 millimeters thick, with 20 to 40 percent of their theoretical modulus, have been produced at speeds of several meters per minute. Tensile strength can be improved from 30 to 500 megapascals and tensile modulus from 1.6 to 20 gigapascals.

**083339 ROLE OF DIFFERENTIAL SCANNING CALORIMETRY AND X-RAY DIFFRACTION IN IDENTIFYING CRYSTAL CONTINUITY IN HIGHLY ORIENTED SAMPLES OF DIE-DRAWN POLYPROPYLENE.** X-ray diffraction and differential scanning calorimetry studies of die-drawn polypropylene have indicated the presence of a crystalline structure which does not identify with any of the usual crystallographic forms and has a melting point slightly below that of the monoclinic  $\alpha$  form. The melting of this structure is stress sensitive and shows that the superheating effect expected from the melting of an extended chain structure, whose chain ends are physically constrained. It is postulated that this structure bridges the gaps between adjacent monoclinic crystal blocks and provides the framework necessary to maintain mechanical stability at temperatures well above that of the glass transition. Moreover, together with taut tie molecules, this structure is considered to be the main source of the high material stiffness. (Author abstract) 26 refs.

**083340 MOLECULAR ORIENTATION IN DRAWN SMECTIC AND CRYSTALLINE ISOTACTIC POLYPROPYLENE.** The drawing behavior of two polypropylene films of different structures was analyzed. The two films differ as a consequence of different quenching conditions. At a low temperature, a biphasic smectic-amorphous system was obtained, when quenching at 100°C produced a biphasic crystalline-amorphous system. The drawing of samples was carried out at 110°C at which temperature the smectic phase is not stable and is transformed into the crystalline  $\alpha$ -form. The initial structure affects the drawing behavior and the properties of the drawn samples. The mechanical, optical, and X-ray analyses clearly show that high molecular orientation is achieved at lower deformations in the initially smectic sample. In particular, the amorphous phase is highly oriented, inducing higher axial elastic modulus. (Edited author abstract) 21 Refs.

## Dyeing

**083341 HOW TO COLOR POLYOLEFINS FOR TEXTILE APPLICATIONS.** Polyolefins employed as textile fibers cannot be colored by conventional dyeing procedures as the polymers do not have an affinity for dyes. The only way is to introduce pigments into the melt during the fiber-forming process. The pigment particles must be small so they do not disrupt the process. Sometimes such particles could affect the physical properties of the fibers. Most polypropylene fibers are colored by adding pigments to the polymer melt during extrusion. Unlike dyes, pigments are more lightfast and heat stable, and they do not tend to migrate or bleed.

## Electric Properties

**083342 ABSORPTION CURRENT AND SURFACE LEAKAGE IN POLYPROPYLENE.** Transient absorption and resorption currents in low-loss polypropylene at fields in the MV/cm range have been resolved into bulk and surface components. The conduction component of bulk current was almost ohmic, whereas the total measured current varied non-linearly with field. No evidence of contact effects or injected charge was found. Conduction is attributed to impurity ions. (Author abstract) 19 refs.

**083345 REACTIVE EXTRUSION OF POLYPROPYLENE I: CONTROLLED DEGRADATION.** Polypropylene was degraded by injection of a free-radical initiator during extrusion. Molecular weight distribution, molecular weight averages, and melt flow index were measured to see the effect of initiator concentration (0.00 to 0.04 wt%), temperature (200 and 220°C), and screw rpm (31 and 44). Initiator concentration was the most significant variable. In all cases, increased initiator concentration degraded the high molecular weight tail of the polypropylene and narrowed the molecular weight distribution. Melt flow index varied linearly with initiator concentration beyond 0.01 wt% initiator. Reaction temperature had no effect on the measured properties of the extrudate. (Edited author abstract) 29 refs.

Suwanda, D. (Univ of Toronto, Toronto, Ont, Can); Lew, R.; Balke, S.T. *J Appl Polym Sci* v 35 n 4 Mar 1988 p 1019-1032.

**083346 REACTIVE EXTRUSION OF POLYPROPYLENE II: DEGRADATION KINETIC MODELING.** A kinetic model for the free-radical-initiated molecular weight degradation of polypropylene was further developed. The model has a single variable parameter, the initiator efficiency,  $f$ . Assumptions were detailed, new comparisons with experimental data presented, and model sensitivity to the value of  $f$  evaluated. The model was found to provide a good description of both molecular weight distribution and molecular weight average data from degradations carried out in a single-screw extruder at 200 and 220°C. Data at 0.04 wt% initiator feed concentration were fit and the resulting  $f$  value used to predict results of 0.01 wt% and 0.02 wt%. (Edited author abstract) 17 refs.

## Fiber Reinforcement

**083347 CRYSTALLIZATION BEHAVIOUR AND MECHANICAL PROPERTIES OF POLYPROPYLENE-BASED COMPOSITES.** The influence of glass fibers on the primary nucleation process, isothermal radial growth rate of spherulites and overall kinetic rate constant of isotactic polypropylene (iPP) has been examined. The polypropylene was also modified by means of acrylic acid (iPP\*) in order to improve the adhesion between the matrix and the fibers, and the relative properties were compared with those concerning the composites having as matrix plain iPP. Moreover the mechanical properties of injection-moulded composites containing iPP and iPP\* have been studied. These properties improved on increasing the fiber content. It was found that for the same glass-fiber content better values of the elongation at break and creep are observed in the case of reinforced polypropylenes having as matrix acrylic acid modified polypropylene. (Author abstract) 10 refs.

## Filaments

**083348 FIBRILLATION AND FIBRIL NETWORK FORMATION OF POLYPROPYLENE.** The degree of fibrillation of a polypropylene flat yarn which has undergone high stretching and heat relaxation was found to be more directly representable by the longitudinal tear strength and by the length of the split which developed when the flat yarn was folded at an angle of 180 degrees along the direction of the molecular orientation, than by more fundamental factors, such as the degree of crystallization. The split yarn manufacturing conditions were defined numerically on the bases of those measured data, yielding a direct relation to the degree of fibrillation. The most important points to produce the yarn are to suppress the progressive fibrillation and to make the well-balanced properties by relaxation and heat setting after splitting. These properties include composition of material, the radiant heat for surface treatment, and the stress relaxation. (Edited author abstract) In Japanese. 7 refs.

## Fillers See Also COMPOSITE MATERIALS—Electric Properties; PLASTICS PRODUCTS; POLYOLEFINS—Flame Resistance.

**083349 EFFECT OF FILLER SHAPE ON MODULI OF ORIENTED POLYPROPYLENE COMPOSITES.** The relations between the modulus of oriented polypropylene filled with granular (calcium carbonate), flake (talc) or fiber like (sepiolite) fillers, the void volume at the filler/polymer interface, and the filler effects were investigated. The relative moduli of oriented composites are reasonably accounted for by the modified Halpin-Tsai equation which contains the factors of: polymer matrix orientation, filler effect, void volume at filler/polymer interface for the granular, flake and fiber-like fillers. (Edited author abstract) In Japanese. 10 refs.

Mitsuishi, Kazuta (Industrial Technology Cent of Okayama Prefecture, Okayama, Jpn); Kodama, Soji; Kawasaki, Hitoshi; Tanaka, Makoto. *Kobunshi Ronbunshu* v 44 n 7 1987 p 551-555.

**083350 EFFECT OF FILLER PROPERTIES ON THE MODULUS OF ORIENTED POLYPROPYLENE FILLED WITH FLAKE-LIKE FILLERS.** Flake-like fillers with various particle sizes (talc: 0.8, 3.3, 10.0, 25.5  $\mu$ m; mica: 15, 32, 98, 320, 730  $\mu$ m) were mixed with polypropylene (PP). The effect of flake-like filler properties such as filler aspect ratio, filler size, and filler content on the modulus of oriented PP composites was investigated. The relative modulus is shown to be determined by the following factors: (1) orientation factor of

the PP matrix, (2) filler properties (filler content, aspect ratio, modulus), and (3) void properties (void volume, void length). The filler size dependence can be clearly recognized, showing an increase in  $E_c^d/E_c^d$  as filler size decreased for PP/talc and PP/mica systems. (Edited author abstract) 20 refs.

**083354 EFFECTS OF UNIAXIAL STRETCHING  
AND SHRINKAGE ON PROTON SPIN-LATTICE  
AND SPIN-SPIN RELAXATION TIMES OF ISO-  
TACTIC POLYPROPYLENE.** An isotactic polypropylene film was stretched at 120°C in poly(ethylene glycol) and thermally shrunk at various temperatures. Proton spin-lattice,  $T_1$ , and spin-spin,  $T_2$ , relaxation times were measured using a broad line pulse spectrometer operating at 19.8 MHz in the temperature range 40°C-100°C. The temperature of  $T_1$  minimum shifts to higher temperatures and the value of  $T_1$  minimum increases in magnitude as the stretching ratio is increased. In contrast the temperature of  $T_1$  minimum shifts to lower temperatures as shrinkage is increased, whereas the value of  $T_1$  minimum increases in magnitude because of the increase in crystallinity during shrinkage. **Freezing**

**083357 IMPROVEMENT OF THE FREEZE RE-  
SISTANCE OF POLYPROPYLENE.** An examination is made of the influence of the molecular weight of the rubber and of the fabrication methods on  $T_{br}$  of freeze-resistant polypropylene compositions. The experimental results show that with the use of polysiloxane rubbers of various structures and having molecular weight of  $10^5$ - $10^6$  it is possible to obtain polypropylene compositions of improved freeze resistance, having  $T_{br} < -60^\circ$ . The greatest lowering of  $T_{br}$  was obtained with the use of polysiloxane rubbers having molecular weight  $\geq 5 \cdot 10^5$  (SKTV, E-301). The freeze resistance of compositions containing these rubbers exceeds by  $10$ - $15^\circ$  the best reported results in this field. 4 refs.

**Glass Transition**

**083358 CALORIMETRIC RELAXATION AND  
GLASS TRANSITION IN POLY(PROPYLENE GLY-  
COLS) AND ITS MONOMER.** The glass transition temperature  $T_g$  of propylene glycol (PG) and poly(propylene glycols) (PPGs) of molecular weight up to 4000 has been measured by differential scanning calorimetry, and the activation energy and change in heat capacity  $\Delta C_p$  have been determined in the glass transition range. The activation energy increases with an increase in the molecular weight of the polymer, and  $\Delta C_p$  measured at a fixed heating rate decreases. The increase in  $T_g$  with molecular weight is remarkably more rapid for poly(propylene glycols) than for other polymers, and a limiting value of  $T_g$  is reached for a chain containing 20 monomer units.

These results are discussed in terms of the Fox-Flory and the entropy theories. The calorimetric relaxation times are comparable with the extrapolated dielectric relaxation times. The initial increases of  $\Delta C_p$  from PG to PPG 200 is attributed to the decrease of H-bonding sites from 12 in 3 monomers to 4 on polymerization to PPG 200 and further decrease with increase in molecular weight to an increasingly large amplitude of the  $\beta$ -process at  $T < T_g$ . (Author abstract). 22 Refs.

**Grafting**

**083359 SYNERGISTIC EFFECTS OF UREA WITH  
POLYFUNCTIONAL ACRYLATES FOR ENHANC-  
ING THE PHOTOGRAPHING OF STYRENE TO  
POLYPROPYLENE.** The current work reports the use of urea for accelerating the photografting of styrene in methanol to polypropylene in the presence of benzoin ethyl ether as sensitizer. More importantly, when polyfunctional monomers such as trimethylol propane triacrylate (TMPTA) are included in these solutions in additive amounts, their presence is shown to induce synergistic effects with urea leading to extremely large grafting enhancement. Urea and TMPTA independently increase photografting yields when present as additives. Inclusion of both additives in the same monomer solution leads to a synergistic effect in grafting. The remarkable result in all of these studies is the very large enhancement in photograft on the addition of TMPTA, especially in the presence of urea. 11 refs.

**083362 NACHDRUCKFREIES SPRITZGIESSEN  
VON POLYPROPYLEN.** [Injection Moulding of Polypropylene Without Packing Effect of Cooling Rate on the pVT Diagram]. It is shown, using an example taken from a large series of measurements, that in the injection moulding of 2 mm thick polypropylene plates without packing the required pressure variation during the cooling phase cannot be correctly estimated from pVT diagrams measured for relatively low rates of cooling in the stationary melt. Measurements and calculations indicate that, because of the faster cooling rates in injection

moulding, the literature values for the temperature ranges in which crystallization occurs in the interior of the plate must be shifted to lower temperatures to obtain correct results; on the other hand, in the highly orientated outer zones of the plate, notwithstanding the very high rates of cooling, they must be shifted to higher temperatures owing to shear-induced crystallization. (Author abstract) 7 refs. In German.

## Ion Exchange

**083364 STRUCTURAL FEATURE AND EXCHANGE KINETICS OF CARBOXYLATED POLYPROPYLENE ION EXCHANGE RESIN.** The present article deals with the exchange process of bivalent metal ions, such as  $Zn^{2+}$ ,  $Cd^{2+}$  and  $Hg^{2+}$ , etc., taken up by non-crosslinked carboxylated polypropylene (CPP) resin. The control factor of the exchange rate deduced from the kinetic data is governed basically by the chemical reaction rather than the mass transfer effect particle diffusion and/or liquid film diffusion. In solution, all the graft chains in the outer shell of a CPP resin could form a —quasi-macromolecular solution— domain. The opinion further demonstrates the structural pattern of CPP resin proposed in earlier paper. (Author abstract) 6 refs.

**083365 ROZWOJ PRZEMYSTOWYCH METOD OTRZYMYWANIA POLIPROPYLENU.** [Developments in the Commercial Manufacture of Polypropylene]. A comparative evaluation of the commercial methods of polypropylene polymerization in solution in liquid monomers (bulk polymerization) and in the gaseous phase have been compared with regard to their technological convenience, polymer yield and capital costs. The advantages resulting from replacing the classical catalysts of generation I with much more active catalysts of generation II and in particular those of generation III ( $TiCl_4$  deposited on magnesium chloride modified with electron donors) have been discussed. These advantages consist in a significant simplification of the technological process due to elimination of a number of operations, lower consumption of raw materials and energetic media and higher yield and stereospecificity of PP. The best prospects in this respect have bulk polymerization and polymerization in the gaseous phase with the application of highly active catalysts of generation III. (Edited author abstract) 51 refs. In Polish.

## Measurements

**083366 INFRARED DICHROISM AND VISIBLE-ULTRAVIOLET DICHROISM STUDIES ON ROLLER-DRAWN POLYPROPYLENE AND POLYETHYLENE SHEETS.** The crystal and amorphous orientation functions of polypropylene (PP) and high-density polyethylene (HDPE) sheets, stretched by the roller-drawing technique, were measured by means of infrared dichroism and visible-ultraviolet dichroism. The molecular chains in the crystalline and amorphous regions lined up parallel to the draw direction in the roller-drawing process. At higher draw ratio ( $\lambda > 7-13$ ), the crystal orientation function approached a constant value, whereas the amorphous orientation function increased monotonically with draw ratio. The orientation function calculated from visible-ultraviolet dichroism decreased greatly with decreasing length of solute (dye) molecules. The reasons for this phenomenon are discussed. (Edited author abstract) 38 refs.

## Mechanical Properties

**083367 FLAME RETARDATION OF POLYPROPYLENE: EFFECT OF ORGANOANTIMONY COMPOUNDS ON THE STRUCTURAL AND MECHANICAL PROPERTIES.** Structural properties of polypropylene (PP) filled with flame-retardant (FR) organoantimony compounds, viz., triphenylstibinedibromide and triphenylantimony (V) derivatives of tribromo-, trichloro-, and pentachlorophenols at 5-20 phr additive loading, were investigated through differential thermal analysis (DTA), and X-ray diffraction (XRD) studies. Incorporation of flame retardant in PP has decreased the melting temperature and heat of fusion of PP. Crystallization peak and the onset temperature, crystallization rate and crystallite size are also influenced by the addition of these compounds. The percent crystallinity obtained by XRD is in good agreement with that obtained by DTA. The tensile properties of the flame-retardant-filled PP are also studied, and an attempt has been made to correlate the tensile properties with that of structural changes in polypropylene. Fracture mechanism of flame-retardant-filled PP has been investigated with the help of a scanning electron microscope. (Edited author abstract) 35 refs.

**083369 RELATIONSHIPS BETWEEN INJECTION MOULDING CONDITIONS, MICROMORPHOLOGY AND IMPACT CONDITIONS, MICROMORPHOLOGY AND IMPACT PROPERTIES OF POLYPROPYLENE: I. A TYPICAL COMMERCIAL GRADE.** The morphology of isotactic propylene homopolymer injection moldings has been varied by systematically changing carefully controlled processing conditions. A range of analytical techniques was used to characterize the micromorphology of the injection moldings and, in particular, the surface morphology, which has a pronounced effect on impact properties. The impact properties of moldings were determined by instrumented falling-weight and instrumented Izod impact test methods and results were used to establish relationships between

processing conditions, micromorphology and impact behavior. The micromorphologies associated with poor impact toughness are clearly identified. (Author abstract) 23 refs.

Murphy, M.W. (Brunel Univ, Uxbridge, Engl); Thomas, K.; Bevis, M.J. *Plast Rubber Process Appl* v 9 n 1 1988 p 3-16.

**083370 STUDY OF VISCOELASTIC RELAXATION IN AMORPHOUS POLYPROPYLENE NEAR  $T_g$  BY DYNAMIC LIGHT SCATTERING AND SHEAR CREEP.** Polarized photon correlation measurements of completely amorphous polypropylene at temperatures between 268 and 293 K are reported. The time correlation functions of density fluctuation caused by the local segmental motion have been represented by the Kohlrausch-Williams-Watts functions. The theory of Wang and Fischer enables us to compute the longitudinal compliance from the time correlation of the density fluctuation. The retardation spectra  $L(\log \tau)$  are calculated also formally. We find the Kohlrausch exponent of longitudinal compliance from dynamic light scattering agrees rather well with that determined from the local segmental mode contribution to the shear creep. The combined light scattering and mechanical data are examined in the light of the coupling model of relaxation. The predictions of the model account for the time correlation function observed by light scattering and the time dependence of the creep compliance obtained by mechanical measurements. The extra prediction of the model can explain the occurrence of two shift factors and relate them quantitatively, in agreement with experimental data. (Edited author abstract) 35 refs.

**083371 TENSILE FLOW STRESS MODEL FOR ORIENTED POLYPROPYLENE.** Many solid-phase processing and forming operations for polymers require tensile stretching forces to produce flow. To make forming operations practical, a knowledge of the flow stress of the polymer is required. This paper presents a simple formulation for predicting the flow stress of polypropylene in the oriented direction as a function of the controlling parameters, which are strain rate, temperature, and deformation ratio. It will be shown that the experimental flow stress data may be formulated in a way that is similar to the constitutive laws for metals. Equations for metals relating flow stress to strain rate, flow stress to strain, and flow stress to temperature are compared with an equivalent formulation for oriented polypropylene. The experimental conditions, chosen to develop the constitutive equations, reflect practical forming conditions. The deformation ratios (i.e., strains) were varied from 6 to 14. (Edited author abstract) 12 refs.

## Microstructure

**083372 MICROSTRUCTURE OF ISOTACTIC POLYPROPYLENE PREPARED WITH HOMONEOUS CATALYSIS: STEREOREGULARITY, REGIOREGULARITY, AND 1,3-INSERTION.** Regioirregularly arranged units have been observed by  $^{13}C$  NMR analysis of isotactic polypropylene prepared in the presence of either racemic ethylenebis(4,5,6,7-tetrahydro-1-indenyl)dichlorozirconium or racemic ethylenebis(indenyl)dichlorozirconium and methylalumoxane. However, the stereochemical placement of the regioirregular units is controlled by the catalyst so that one can speak of more or less stereoregular placement of regioirregular units. The  $\eta^5$  ligands of zirconium affect the stereochemical and regiochemical structure of the polymer. 1,3-Propene insertion has also been observed at a relatively high polymerization temperature. (Author abstract) 32 refs.

617-622.

v 22 n 9 Sep 1987 p 3118-3128.

**083373 MICROTACTICITY DISTRIBUTION OF POLYPROPYLENES PREPARED WITH HETEROGENEOUS ZIEGLER-NATTA CATALYSTS.** The microstructure of the isotactic parts of various polypropylene has been studied by  $^{13}\text{C}$  NMR spectroscopy. The isotacticity of the isotactic parts as determined by the mmmm pentad sequence ('microisotacticity') increases as the stereospecificity of the catalysts (isotactic index, II) employed increases. Several polypropylenes prepared with titanium-based catalysts were fractionated by using an elution column technique. The fractionation results show that two isospecific active centers reside in such catalysts. (Edited author abstract) 12 refs.

## Molecular Structure

**083377 DOMINANT INTERACTIONS IN THE CONFORMATION OF ISOTACTIC POLYPROPYLENE: 1. INTRACHAIN ENERGY.** A calculation is presented of the intrachain component of the conformational energy of isotactic polypropylene. Multiple minima are found for the energy as a function of the three torsional angles, with a strong dependence noted on the rotation of the methyl group. A comparison is made between the energies of ordered and disordered chain conformations constructed to produce the experimentally observed  $3_1$  helix. (Author abstract) 28 refs.

**083379 PHASE SEPARATION IN INCOMPATIBLE POLYMER BLENDS: POLYPROPYLENE-POLYETHYLENE SYSTEM.** The morphology of polypropylene-polyethylene blends has been investigated in the as-prepared state by employing interface distribution functions to evaluate their small angle X-ray scattering. While the morphology of the PP (within the investigated composition range) is not altered by the presence of finely dispersed PE, the morphology of the PE component is strongly dependent on composition. Below a PE weight fraction of 0.3 the PE crystal thickness increases with increasing PE content. Concurrently the lattice distortion decreases. (Author abstract) 19 refs.

## Order-Disorder

**083380 DEFORMATION INDUCED ORDER-DISORDER TRANSITION IN ISOTACTIC POLYPROPYLENE.** Isotactic polypropylene (i-PP) has been deformed by uniaxial compression to draw ratios up to  $16\times$ , and at draw temperatures from 30°C to 140°C. An order-disorder transition in the crystals is observed at draw temperatures well above the stability limit, 70°C, reported for the disordered phase. Furthermore, this disordered phase (called smectic) is found to induce ductility and improve the efficiency of draw. The deformation induced smectic phase has been characterized using WAXS DSC, and on-line compression load versus draw ratio measurements. In consequence, a set of process conditions are offered to optimize draw. A mechanism for plastic deformation of i-PP is also suggested, using the smectic phase as a probe. (Edited author abstract). 18 Refs.

## Oxidation

**083381 REASONS FOR THE CHANGE IN THE EFFECTIVE REACTION CONSTANTS OF CHAIN PROPAGATION AND TERMINATION IN THE IN-**

**DUCTION PERIOD OF OXIDATION OF ISOTROPIC AND ORIENTED ISOTACTIC POLYPROPYLENE.** The rate constants of the reactions of propagation and termination of the oxidation chains of PP films with different degrees of oxidation and stretching have been determined in absence and presence of a photo-initiator with variation in the spectral composition of the light and the duration of irradiation. The value of the rate constant of death of the radicals depends on the mode of photo-initiation which is connected with the heterogeneity of the course of the reaction of death of the radicals in the polymer volume. (Author abstract) 21 refs.

**083382 SIMULATION OF POLYCHROMATIC KINETICS OF THE PROPAGATION STEP OF THE CHAIN OXIDATION REACTION IN STRAINED POLYPROPYLENE OF THE BASIS OF A ROTATIONAL ISOMER MODEL.** The change in the mean intramolecular rate constant for the propagation step of the oxidation reaction in the amorphous phase of oriented polypropylene subjected to stretching strain is simulated with a computer. The value of this constant depends on the type of function for the length distribution of the straight chains and on the size of the amorphous part, which can introduce a contribution to the structural sensitivity of the kinetic parameters for the oxidation of amorphous-crystalline polymers. The constant decreases on deformation of the thermodynamically rigid chains and passes through a minimum on deformation of the flexible chains. (Author abstract) 21 refs.

**083384 KINETIC AND DIFFUSION PARAMETERS OF OXIDATION OF POLYPROPYLENE.** The kinetic patterns of oxidation of isotactic PP have been studied in presence of the initiator dicumyl peroxide and in the auto-oxidation regime. The kinetic and diffusion parameters of oxidation have been obtained. It is established that in the course of oxidation the rate constant of breakdown of the hydroperoxide groups to radicals increases, which is due to accumulation of other oxygen-containing groups in the polymer. (Author abstract) 14 refs.

Kirgin, A.V. (USSR Acad of Sciences, USSR); Shilov, Yu.B.; Denisov, Ye.T.; Yefimov, A.A. *Polym Sci USSR* v 28 n 10 1986 p 2486-2493.

**083385 AUTOXIDATION KINETICS OF ATACTIC POLYPROPYLENE IN BULK.** The kinetics of the reaction between atactic polypropylene (APP) and oxygen in bulk at temperatures ranging from 170 to 210°C and oxygen partial pressures from 160 to 760 torr have been studied by thermal differential analysis. The reaction takes place in two successive steps, both giving hydroperoxide groups as products. Partial reaction orders with respect to APP and oxygen for the first step, which corresponds to

## Mixing

**083374 CORRELATION OF THE POWER NUMBER OF HELICAL RIBBON AGITATOR FOR POWDERY POLYPROPYLENE.** In this paper, the agitating power for powdery polypropylene has been correlated by using dimensional analysis. For helical ribbon agitator, the power number can be expressed by the same form of power number equation as for liquid. In view of the non-Newtonian characteristics of powdery material, its apparent viscosity is given as a function of the rotating speed. The result of regression showed that the difficulty in the experimental measurement of the apparent viscosity could be avoided. (Edited author abstract) 6 refs. In Chinese.

**083375 STATES OF ORDER IN BLENDS OF ISOTACTIC POLYPROPYLENE AND ISOTACTIC POLY(1-ETHYLETHYLENE).** The thermodynamic miscibility of the components in the noncrystalline state is discussed with respect to the Flory Huggins interaction parameters  $\chi_{12}$ . In the blends  $\chi_{12}$  was found to be zero for any composition, thermodynamic miscibility in the melt as well as in the solid noncrystalline regions can be excluded. X-ray and thermoanalytic studies gave no evidence of the formation of mixed crystallites, but show that the lattices of the it-PP and it PB crystallites are deteriorated. From the melt it-PB crystallizes in the tetragonal modification II and it-PP in the monoclinic modification I. From solutions the orthorhombic modification III of it-PB and modification I of it-PP are obtained. (Edited author abstract) 27 refs.

## Molding

**083376 NON-DESTRUCTIVE ULTRASONIC EVALUATION OF  $\text{CaCO}_3$ -FILLED POLYPROPYLENE MOULDINGS.** The dynamic elastic moduli and Poisson's ratio of calcium carbonate-filled polypropylene mouldings have been determined for a continuous range of filler loadings of between 0 and 40% volume fraction. Measurements were made non-destructively on bulk samples in the form of plates 2 cm  $\times$  2 cm square and 3 mm thick, at 5 MHz. The composition dependences of the elastic properties are compared with the Hashin and Shtrikman bounds for two-phase materials. All data were in close correspondence with the lower bound, suggesting that the fill particles were well dispersed, relatively free of agglomeration, well bonded to the matrix, and that particle sizes were much less than  $\lambda/4$ , i.e. much less than 100  $\mu\text{m}$ , where  $\lambda$  is the wavelength of compressional waves. (Author abstract) 13 refs.

Bridge, B. (Brunel Univ, Engl); Cheng, K.H. *J Mater Sci*

the uncatalyzed attack of a C-H tertiary bond to give a hydroperoxide, are one and two, respectively. In the second step, interpreted as another attack on a tertiary C-H by oxygen, catalyzed by a neighboring hydroperoxide group, reaction orders are one and one-half for APP and oxygen, respectively. Activation parameters have been determined and a reaction sequence is proposed. Hydroperoxidized APP subsequently decomposes via a zero-order process giving methylketone groups as its main product. An interpretation of this process is also given. (Author abstract) 23 refs.

**083386 CHARACTERISTIC FEATURES OF SOLID-PHASE PHOTOOXIDATION OF ISOTACTIC POLYPROPYLENE AND THE EFFICIENCY OF PHOTOINITIATORS.** The rate of decay of macroperoxy radicals  $PO_2$  formed in polypropylene by photo-initiated transformations of various initiators has been measured under conditions of long reaction chains of oxidation. New effects specific for oxidation proceeding in the solid phase have been found: the dependence of the rate constant characteristic for second-order decay of  $PO_2$  on the irradiation time, on initial concentration of radicals, and on their mutual distance. A new kinetic law of radical decay, generally valid for various initiators, has been established such that the chain termination does not follow the second-order mechanism. ## Phase Transitions

**083388 PHASE CHANGES IN ISOTACTIC POLYPROPYLENE MEASURED BY MICROHARDNESS.** The object of the present study is to examine the influence of polymorphic changes on the values of MH. For this purpose isotactic polypropylene was selected as a material which can crystallize into two polymorphic forms: the  $\alpha$  (monoclinic) and  $\beta$  (hexagonal). Microhardness was measured at room temperature using a Leitz tester adapted with a square-pyramidal diamond indenter. The MH value was derived from the residual projected area of indentation. The results show that the MH of the material decreases from about 111 MN  $m^{-2}$  to a value of 90 MN  $m^{-2}$  when passing from the  $\alpha$ - to the  $\beta$ -phase texture. 15 refs.

**083389 EFFECT OF MOLECULAR WEIGHT DISTRIBUTION ON THE PHYSICAL PROPERTIES AND MORPHOLOGY OF POLYPROPYLENE STRETCHED TAPE.** Stretched tape and film were made from isotactic polypropylene homopolymer produced

with SHAC catalyst (Shell High Activity Catalyst). The resins used were nominal 3.5 and 8.0 melt flow (MF) resins with narrow, medium, and broad molecular weight distributions (MWD). Measurements were made of tape and film physical properties as a function of MWD and process heat history. Small angle x-ray two-theta scans through the meridional direction were done to obtain Long Period Spacing (LPS). Long period spacing for an idealized semicrystalline model is the combined distance through both a crystalline lamella and the amorphous region between the lamellae. LPS was correlated to resin melt flow and MWD. Wide angle x-ray scattering techniques using pole figures and Hermans orientation functions were used to determine molecular orientation. Density and physical properties did not change significantly as a function of MWD for the 3.5 and 8 MF tapes. The tenacities of the 8 MF tapes averaged 0.8 gm/denier less than those of the 3.5 MF tapes. The density of the 8 MF tapes was higher than that of the 3.5 MF tape density indicating a higher percent crystallinity for the 8 MF tapes. (Edited author abstract) 16 refs.

**083391 COMPUTER CONTROLLED POLYPROPYLENE STRETCHED TAPE LINE TO INVESTIGATE THE EFFECT OF PROCESSING CONDITIONS ON STRETCHED TAPE MORPHOLOGY AND PROPERTIES.** A computerized stretched tape line has recently been installed at the Shell Westhollow Research Center. Shrinkage decreased as MWD broadened and also with higher on-line annealing temperatures. (Edited author abstract) 3 refs.

Flood, J.E. (Shell Development Co, Houston, TX, USA); Nulf, S.A.; Millsbaugh, K.C.; Lehnen, P. *J Plast Film Sheeting* v 4 n 1 Jan 1988 p 8-26.

**083392 MOLECULAR ORIENTATION OF POLYPROPYLENE BY ROLLING-DRAWING.** An overview is given of the rolling-drawing of polypropylene. It is intended to answer the following questions. What is rolling-drawing? What changes in tensile properties can be expected as a result of this process? What deformation processes occur during rolling-drawing? What are the processing variables and how do these variables relate to the deformation ratio achieved by rolling-drawing? A tensile flow stress relationship was formulated from experimental data for oriented polypropylene. This constitutive equation estimates the flow stress (or yield stress) of the polymer as a function of deformation ratio, strain rate and temperature. (Edited author abstract). 12 refs.

## Production

**083393 POLYPROPYLENE (PP).** The worldwide consumption of PP and of HDPE is roughly equal, and was some 8.4 mio.t for each in 1986, sharing third place behind LDPE/LLDPE and PVC. With an annual growth rate of 5.5%, consumption of PP in 1991 is expected to reach 11 mio. t. Future growth rates for PP are expected to be greater than those of other commodity plastics. The use of PP is limited by heat-deformation resistance, to

temperatures below 120°C, and by the need for greater stiffness and low temperature impact strength in the same material. Above average growth sectors for PP are seen in textile areas like non-wovens, in packaging (films, thin-wall injection mouldings), and in cars. Replacement of the classical suspension process in inert hydrocarbons by processes using high-activity and highly-stereospecific catalysts, and polymerisation in liquid (bulk process) or gaseous polypropylene (gas-phase process) is continuing its advance. In future, because of the many additives and processing aids employed, PP will be predominantly used in pellets. 8 refs.

**083394 SPHERIPOL PROCESS: MAXIMUM SIMPLIFICATION IN POLYPROPYLENE PRODUCTION.** Scientific and technical knowledge acquired in the last years by Montedison-Mitsui Research on high yield catalysts for olefin polymerization, as well as the ability to modify them as a function of the desired performances, has made it possible to design polyolefin production processes ensuring both very low production costs and high quality products. Pilot plant results confirm that the main key to the success of the new polyolefin processes is represented by the high quality, degree of activity and specialization of the catalysts. This major factor is associated with the reliability of plant technological approaches and macromolecular structures serving as model for the product synthesis. Another aspect of economic and social value is that the processes we are dealing with are absolutely irreproachable from the ecological point of view; they do not produce effluents at all. Data show conclusively that the type of catalyst and its utilization, therefore, determine the relationship between process, product quality and efficiency. Comparative investment costs are given. Homopolymer production costs are also presented.

## Radiation Effects

**083396 DOSE RATE EFFECTS IN THE HIGH ENERGY RADIATION INDUCED STEREOREGULARITY CHANGES IN ISOTACTIC POLYPROPYLENE.** The loss of isotactic pentad sequences in predominantly isotactic polypropylene film when subjected to electron beam radiation (dose rate 720 kGy  $h^{-1}$ ) occurs with a G value of 220, i.e. 2.3 times the corresponding G value (94) for an identical sample irradiated with  $\gamma$  radiation, dose rate 4.4 kGy  $h^{-1}$ . Of equal significance, the pattern of non-isotactic pentad sequences formed during irradiation is different at the two dose rates. High dose rates lead to a greater preponderance of syndiotactic sequences. The results suggest that an energy quantum deposited at the high dose rate is more effective in promoting further stereochemical inversion in nearby monomer units. On average five inversions are promoted on mainly alternate monomer units. With  $\gamma$  radiation, an energy quantum promotes on average two inversions with a more random distribution relative to each other, the average distribution in this case being somewhere between adjacent and alternate. (Author abstract) 7 refs.

Barron, Peter F. (Griffith Univ, Nathan, Aust); Busfield, W. Ken; Hanna, John V. *Polym Commun (Guildford Engl)* v 29 n 3 Mar 1988 p 70-72.

**083397 EXTENSIVE STEREOREGULARITY CHANGES INDUCED IN MOLTEN ISOTACTIC POLYPROPYLENE BY HIGH ENERGY RADIATION AND OTHER MORPHOLOGY EFFECTS.** In a recent paper, we described the remarkably large change in tacticity which was observed in highly annealed isotactic polypropylene (PP) as a result of irradiation with gamma rays under ambient temperature and vacuum conditions. We have found that gelation does not occur in PP if the irradiation is carried out above the melting point, hence these conditions allow a more extensive study of the induced stereoregularity changes. This is a preliminary report of the even more remarkable irradiation effects observed in the high temperature experiments, together with some other morphological effects. 8 refs.

**083398 POSITRON ANNIHILATION LIFETIME AND DOPPLER BROADENING STUDIES OF ELECTRON-IRRADIATED POLYPROPYLENE.** The authors used positron annihilation lifetime and Doppler broadening spectra to investigate microstructural changes of polyethylene films before and after electron irradiation. The intensity of the longest lifetime and the shape parameter of Doppler broadening decrease gradually with increase of the irradiation dose. The decrease of positronium formation due to radiation induced defects such as proved by electron spin resonance measurements where a large amount of radicals are observed after irradiation. 10 refs.

Wang, G.-H. (Nanjing Univ, Nanjing, China); Teng, M.-K.; Shen, D.-X.; Yi, C.-Y.; Zhou, Y.-Y.; Lu, Y.-Y.; Wang, H.-W.; Zhu, Y.-Z.; Dou, L. *Phys Status Solidi A* v 106 n 1 Mar 1988 p K1-K6.

**083399 EFFECT OF GAMMA-IRRADIATION ON THE MORPHOLOGY OF QUENCHED ISOTACTIC POLYPROPYLENE.** Wide-angle x-ray diffraction, differential scanning calorimetry and gel-permeation chromatography measurements have been used to investigate the effect of low absorbed doses of  $\gamma$ -radiation, up to 100 kGy, on isotactic polypropylene (iPP). The bimodal endotherm for the sample quenched in iced water was attributed to the presence of both 'smectic' and monoclinic crystalline phases. The changes in the morphology, molecular weight distribution, decrease of melting temperature and heat of fusion with absorbed dose are related to the radiation processes in pure iPP. (Author abstract). 10 Refs.

**083400 ELECTRON RADIATION EFFECTS ON THE ELECTRICAL AND MECHANICAL PROPERTIES OF POLYPROPYLENE.** Capacitor-grade polypropylene film was irradiated in air with a 1-MeV electron beam to different doses up to  $10^8$  rads; the postirradiation effects on the electrical and mechanical properties included the 60-Hz ac breakdown voltage, dielectric constant, and dissipation factor. The dielectric constant and dissipation factor were obtained at five frequencies ranging from 50 Hz to 10 kHz. The tensile properties comprised the Young's modulus, elongation-at-break, and tensile strength. While the electrical and tensile properties were evaluated at room temperature, the dynamic mechanical properties were determined at a frequency of 110 Hz in a temperature range from 12 to 120°C. The results obtained indicate that while the electrical properties remain relatively stable at doses up to  $10^7$  rads, the mechanical properties exhibit a steady decline even at lower dose levels. 18 refs.

Hammoud, A.N. (State Univ of New York, Buffalo, NY, USA); Laghari, J.R.; Krishnakumar, B. *IEEE Trans Nucl Sci* v NS-34 n 6 Dec 1987, 1987 Annu Conf on Nucl and Space Radiat Eff, Snowmass Village, CO, USA, Jul 28-31 1987 p 1822-1826.

**083401 RADIATION CROSSLINKING OF POLYPROPYLENE.** The radiation crosslinking of polypropylene (PP) with several kinds of polyfunctional monomers has been examined. We have found that the polyfunctional monomers can be classified into three types by the electron irradiation dose necessary for crosslinking. In particular, we have developed a new crosslinking method using a specific crosslinking coagent having an acryloyloxy group with a very low required irradiation dose. If this type of monomer is used, 0.5 Mrad is enough to saturate the crosslinking, while the other two types require more than 5 Mrad. The degree of crosslinking is estimated by the gel fraction, modulus of the molten sheet and that of degradation by elongation and oxidation induction time. The crosslinked PP obtained by this method has many good properties, such as a high modulus, large elongation, and high heat resistance. This method may be applied in the manufacture of foamy and other heat resistant materials. (Edited author abstract) 9 refs.

## Solutions

**083402 EFFECTS OF SOLVENT TYPE ON THE CONCENTRATION DEPENDENCE OF THE COMPRESSION MODULUS OF THERMOREVERSIBLE ISOTACTIC POLYSTYRENE GELS.** Solutions of isotactic polystyrene in either trans-decalin or 1-chlorodecane were transformed into gels by quenching from a high temperature (ca. 180°C) to -20°C. The relaxation modulus in compression of these gels was measured over a range of concentrations of from 0.04 g/g to 0.40 g/g. At 22°C, the gels show a double logarithmic stress relaxation rate,  $m$ , which is higher than for PVC and gelatin gel systems. 120 s isochronal modulus concentration diagrams exhibit non-power law behavior, i.e., not only is the general trend such that the double logarithmic slope decreases with increasing concentration, but there are also regions in which abrupt changes in modulus occur over narrow ranges in concentrations. The behavior is interpreted to be inconsistent with a fringed micelle picture of the gel structure. Preliminary results are reported indicating that polymer fraction and temperature of gel formation can significantly affect the modulus of the gels. (Edited author abstract) 17 refs.

## Spectroscopic Analysis

**083403 PRISPEVOK INFRACERVENEJ ABSORPCNEJ SPEKTROSKOPIE K HODNOTENIU KOMPONITNYCH POLYPROPYLENOVYCH VLAKEN.** [Contribution of Infrared Absorption Spectroscopy to Investigation of Composite Polypropylene Fibers]. A quantitative analysis is presented of infrared spectra obtained from polypropylene fibers filled with finely ground limestone. Relationships between filler loading and crystallinity for fibers exhibiting various degrees of deformation are shown. (Author abstract) In Slovak 27 refs.

Michlik, Peter (Vyskumny ustav Chemickych Valken, Svit, Czech); Durcova, Olga; Knotek, Lubomir. *Plasty Kauc* v 24 n 1 Jan 1987 p 11-15.

**083404 TWO-DIMENSIONAL NMR CHARACTERIZATION OF PROPYLENE COPOLYMERS.** Newly developed two-dimensional NMR techniques are used to characterize homopolypropylene and copolymers of propylene with ethylene and butylene. Both homonuclear and heteronuclear shift-correlated experiments have been attempted. The most useful technique for the copolymers is  $^{13}\text{C}$ - $^1\text{H}$  shift correlation, whereby the one-dimensional  $^1\text{H}$ -NMR spectra of these copolymers are completely interpreted for the first time. Although the

$^1\text{H}$  resonances are heavily overlapped, the use of a computerized 'analytical' approach permits pertinent information to be obtained from the one-dimensional  $^1\text{H}$ -NMR spectra. (Author abstract) 38 refs.

**083405 STUDIES OF THE MOBILITY OF PROBES IN POLY(POLYPROPYLENE OXIDE): 1. FLUORESCENCE ANISOTROPY DECAY.** The fluorescence anisotropy decay of a rodlike probe, diphenylhexatriene (DPH), dissolved in 1,2-propanediol and in poly(propylene oxide) matrices with molecular weights 425 and 4,000, is studied using the single-photon-counting technique and synchrotron radiation as the exciting source. The monomolecular reorientation correlation times are compared with previous light-scattering results. It is shown that combining these two techniques, which explore complementary time ranges, the shift factor and WLF parameters for molecular relaxation can be obtained without any further assumptions. The results are in agreement with those obtained from viscoelastic data. (Edited author abstract) 21 refs.

Fofana, Mamadou (CNRS, Paris, Fr); Veissier, Valerie; Viovy, Jean Louis; Monnerie, Lucien; Johari, G.P. *Polymer* v 29 n 2 Feb 1988 p 245-250.

**083406 STUDIES OF THE MOBILITY OF PROBES IN POLY(PROPYLENE OXIDE): 2. EXCIMER FLUORESCENCE TECHNIQUE.** Intramolecular excimer formation of meso-2,4-di(N-carbazolyl)pentane dissolved in two poly(propylene oxides) of molecular weights 425 and 4,000 as well as in 1,2-propanediol (monomer) has been investigated. The intramolecular conformational charge required for the excimer sampling process is shown to be controlled by the segmental motions of the polymer matrices involved in the glass transition phenomenon. The data obtained in 1,2-propanediol have been fitted by a Vogel-type WLF equation. The results show that intermolecular interactions in the monomer lead to a thermal expansion coefficient of the free volume smaller by a factor of about 2 than that of the polymer. (Author abstract) 14 refs.

**083407 STRUCTURE OF HIGHLY ORIENTED POLYPROPYLENE AND ITS EFFECT ON PHYSICO-MECHANICAL PROPERTIES.** The structure of highly oriented polypropylene was studied by X-ray, IR-spectroscopic and thermophysical methods. At elongations  $\lambda > 15$ , the crystallites and the polymer chains in amorphous regions were shown to be fully oriented in the strain direction, while the long period, and the longitudinal and transversal crystallite dimensions were independent of  $\lambda$ . With increasing  $\lambda$ , the crystallinity growth as determined by X-ray exhibits but insignificant growth, whereas that determined by DSC measurements increases by 30%. The effect of the structure of highly oriented polypropylene on the elastic modulus was analyzed. A model of the structure of highly oriented polypropylene is proposed. (Author abstract) 17 refs.

**083408 USE OF INFRARED SPECTROSCOPY FOR DETERMINATION OF POLYPROPYLENE STEREOREGULARITY.** This study examines the application of infrared (IR) spectrometry to the determination of polypropylene (PP) stereoregularity. The use of the absorption bands at  $998\text{ cm}^{-1}$  and  $841\text{ cm}^{-1}$  as indices of isotacticity and bands at  $1167\text{ cm}^{-1}$  and  $973\text{ cm}^{-1}$  as internal references have been explored. Calibration curves relating various absorption ratios to isotacticity as measured by  $^{13}\text{C}$  nuclear magnetic resonance are reported.

The ratios  $A_{998}/A_{973}$  and  $A_{841}/A_{973}$  are the most useful and provide linear correlations with isotacticity. The effect of instrument type on the calibration has been investigated for both dispersive and Fourier transform type IR spectrometers. (Edited author abstract) 23 refs.

**083409 CARBON-13 NMR INVESTIGATION OF LOCAL DYNAMICS IN BULK POLYMERS AT TEMPERATURES WELL ABOVE THE GLASS TRANSITION TEMPERATURE. 2. POLY(PROPYLENE OXIDE) AND LINEAR AND CROSS-LINKED POLY(ETHYLENE OXIDES).** Carbon-13 spin-lattice relaxation time measurements have been performed at two experimental frequencies on the considered polymers, and the data have been analyzed by using the orientation autocorrelation functions developed for polymers and a modified function proposed for poly(vinyl methyl ether) in the preceding paper. As observed in the latter compound, a fast motion of the internuclear vector has to be considered and has been assigned to a libration of limited extent about the rest position. The temperature dependence of the segmental motions proves that these modes are involved in the glass-rubber transition process. Furthermore, the effect of cross-linking on the dynamics of poly(ethylene oxide) segments has been studied. (Author abstract). 23 Refs.

## Spectrum Analysis

**083410 HIGH-RESOLUTION SOLID-STATE  $^{13}\text{C}$  NUCLEAR MAGNETIC RESONANCE STUDY OF ISOTACTIC POLYPROPYLENE POLYMORPHS.** High-resolution  $^{13}\text{C}$  nuclear magnetic resonance spectra are reported for three solid samples of isotactic polypropylene (i-PP): (i) the  $\alpha$ -crystalline form (monoclinic), (ii) the  $\beta$ -crystalline form (hexagonal), and (iii) the mesomorphic or smectic form of i-PP. These spectra were obtained using magic angle spinning, high-power proton dipolar-decoupling and cross-polarization techniques, and for the  $\beta$ - and smectic forms of i-PP constitute the first reported high-resolution solid-state spectra. The spectrum of the  $\alpha$ -crystalline form shows well resolve splittings (1 ppm) of the methyl and methylene carbon resonances. These splittings are absent in the spectra observed for the  $\beta$ - and smectic forms of i-PP. (Edited author abstract) 30 refs.

**083411 HEPTAD CONFIGURATIONAL ANALYSIS OF  $^{13}\text{C}$  N.M.R. SPECTRA IN HIGHLY ISOTACTIC POLYPROPYLENE.**  $^{13}\text{C}$  nuclear magnetic resonance (n.m.r.) spectra were obtained at 67.8 MHz for highly isotactic polypropylene polymerized with a Ziegler-Natta catalyst. The tactic heptad peaks observed in the methyl region of the spectrum were assigned on the basis of the gamma effect of chemical shift and by using the Suter-Flory RIS model of polypropylene conformations. The mechanism of propylene polymerization were analyzed from the values of triad and pentad tacticities. The two-site model, with its three parameters optimized, reproduced well the observed relative areas of pentad and heptad peaks in the region of methyl carbon resonances. (Edited author abstract) 16 refs.

## Stability

**083412 MEASUREMENT OF THERMO-OXIDATIVE STABILITY OF ISOTACTIC POLYPROPYLENE BY ISOTHERMAL LONG-TERM DIFFERENTIAL THERMAL ANALYSIS.** The thermo-oxidative stability of isotactic polypropylene with different antioxidant concentrations between 0% and 0.1% has been studied using isothermal long-term differential thermal analysis (ILDTA). Aging tests in a circulating-air oven at 140°C showed that the loss of thermo-oxidative stability with increasing aging time was nearly linear. So the state of thermo-oxidative deterioration of isotactic polypropylene can be estimated by measurement of residual life time in an ILDTA experiment. The end of the oven life of polypropylene coincided with the loss of mechanical properties which was confirmed by a long-term tensile test at 100°C and 120°C. (Edited author abstract) 7 refs.

## Stabilizers

**083414 SYNERGISM OF HINDERED AMINE LIGHT STABILIZERS AND UV-ABSORBERS.** The synergism of hindered amine light stabilizers (HALS) and UV-absorbers is very important in the practical photo-stabilization of polymers. As very little is known, however, the relationship between the composition of the mixture of the two kinds of light stabilizer and its photo-stabilizing efficiency was investigated in four common polymers. A high level of synergism was observed in polypropylene, high density polyethylene and ABS resin. A moderate synergistic effect was obtained in polystyrene. The maximum efficiency was observed at mixing ratios of hindered amine light stabilizer to UV-absorber of about 75:25 in polypropylene and high density polyethylene, 90:10 in ABS resin and 80:20 in crystal polystyrene. (Edited author abstract) 21 refs.

## Stresses

**083416 EFFECT OF DRAW RATE ON THE STRESS-STRAIN BEHAVIOUR OF POLYMERS.** A new phenomenon has been observed in the tensile deformation of polymers, including polypropylene, poly(ethylene terephthalate) and polyethylene. It has been seen that when draw rate is larger than a critical value, Young's modulus, yield stress and other parameters associated with the drawing response of these polymers decrease rapidly with the increasing draw rate; the normal time-temperature superposition principle does not appear to hold in this case. Further it can be shown that this decrease in modulus and yield stress is not caused by a temperature rise during drawing; the tensile deformation process before yield is largely isothermal. As an alternative, a change in the yield mechanism is suggested as a reason for the decrease in modulus and yield stress. (Edited author abstract) 14 refs.

**083417 WHOLE-PATTERN APPROACH TO STRUCTURE REFINEMENT PROBLEMS OF FIBROUS MATERIALS. APPLICATION TO ISOTACTIC POLYPROPYLENE.** Following up an idea developed in a previous paper, the crystal structure of the  $\alpha$  form of isotactic polypropylene (IPP) has been refined by a least-square fitting procedure by using X-ray diffraction fiber data and considering the fiber spectrum as a whole. This approach represents an extension of the Rietveld method from the one-dimensional case (powders) to a two-dimensional case (fibers). In spite of structure complexity, low resolution, and reflection overlap, well-distinguishable fits have been obtained by considering the two structure models  $P2_1/c$  and  $C2/c$  which are very closely related to each other. A reliable chain model of  $3_1$  symmetry was obtained having C-C-C chain angles of 116.9 and 112.4°, chain torsion angles of 178 and 59°, and methyl-to-chain valence angles of 108.2°. (Author abstract) 22 refs.

**083418 DISTRIBUTION OF MOLECULAR ORIENTATION AND STABILITY OF PEROXY RADICALS IN THE NONCRYSTALLINE REGION OF ELONGATED POLYPROPYLENE.** The angular dependent ESR spectra of peroxy radicals in noncrystalline regions of elongated polypropylene are successfully observed following UV and  $\gamma$ -irradiation at low temperatures. The ESR spectra of mobile radicals obtained by subtracting the ESR spectra after annealing from those before annealing can be simulated from the calculated spectra of the partially oriented paramagnetic centers. The shape of the resulting spectrum changes drastically with the annealing temperature. It is found that the more mobile radicals have the lower degree of orientation. **083420 ESTIMATION OF  $\sigma_E$  AND  $\alpha$ - AND  $\beta$ -FORM POLYPROPYLENE.** Several reports have been published on the fold surface free energy  $\sigma_E$  of  $\alpha$ -form isotactic polypropylene (PP). However, few reports can be found concerning the  $\beta$ -form. These values are necessary to the discussion of lamellar growth and also to the consideration of  $\beta$ -modification change. For this purpose, SAXS (small angle x-ray scattering) and DSC (differential scanning calorimetry) measurements were made on  $\alpha$  and  $\beta$ -form PP specimens which possess a preferred lamellar orientation. The oriented specimens were grown by temperature-gradient crystallization without addition of any  $\beta$ -nucleator. 9 refs.

**Thermooxidation**

**083421 THERMOXIDATIVE DEGRADATION OF POLYPROPYLENE.** The thermooxidative behavior of atactic and isotactic polypropylene under dynamical thermooxidative conditions has been studied. It has been established that, with the increase of the heating rate, the development of the oxidative processes are diminished and consequently a modification in the reaction mechanism takes place. One can notice at the same time that the oxidative processes are more intense in the case of the atactic polymer. The 5-15°C/min heating rates determine significant differences between the thermal behavior of the samples, permitting the elaboration of the standard curves useful in fast determination of the atactic content of the industrial products by routine analysis. **Thin Films**

**083422 EFFECT OF THE MOLECULAR CHARACTERISTICS OF POLYPROPYLENE ON PROPERTIES OF ORIENTED FILMS.** This study is devoted to ascertaining the effect of the molecular weight (M) and molecular weight distribution (MWD) of PP films on the fibrillation process and the physicochemical properties of oriented materials. The object of study was PP films 70  $\mu$  thick, made from a melt of polymer which had various values of M and MWD. Experimental data indicate that the ability of films to fibrillate is determined by nonuniform stresses, which depend on M (Molecular Weight) and MWD (Molecular Weight Distribution). With increase in M and decrease in M<sub>w</sub>/M<sub>n</sub>, formation of a uniform inter- and intrafibrillar structure takes place, which ensures high physicochemical properties of the film materials. 4 refs.

**083425 REGIOSELECTIVELY MODIFIED STEREOREGULAR POLYSACCHARIDES X. EQUILIBRIUM POLYMERIZATION OF 1,6-ANHYDRO-2-O-BENZYL-3,4-DIDEOXY- $\beta$ -D-THREO-HEXOPYRANOSE.** A synthetic linear polysaccharide having one axial hydroxyl group in position 2 in each repeating unit, 3,4-dideoxy-(1 $\rightarrow$ 6)- $\alpha$ -D-threo-hexopyranan (3), was synthesized by cationic ring-opening polymerization of 1,6-anhydro-2-O-benzyl-3,4-dideoxy- $\beta$ -D-threo-hexopyranose (1), followed by debenzoylation. The polymerization of 1 using phosphorus pentafluoride as initiator at temperatures ranging from +60 to 0°C gave the stereoregular polymer with an  $\alpha$ -anomeric configuration, 2-O-benzyl-3,4-dideoxy-(1 $\rightarrow$ 6)- $\alpha$ -D-threo-hexopyranan (2). The apparent polymerization rate and copolymerization reactivity of 1 were high, but the polymer yield was relatively low owing to the high equilibrium monomer concentration of 1 ( $[M]_e = 0.31 - 0.54 \text{ mol l}^{-1}$  at  $-60^\circ\text{C}$ ). (Edited author abstract) 21 refs.

**083428 STUDIES ON CHITIN. 13. NEW POLYSACCHARIDE/POLYPEPTIDE HYBRID MATERIALS BASED ON CHITIN AND POLY( $\gamma$ -METHYL-L-GLUTAMATE).** A new type of polysaccharide/polypeptide hybrid material, chitin derivatives having polypeptide side chains, was prepared by the graft copolymerization of  $\gamma$ -methyl-L-glutamate N-carboxy anhydride (NCA) onto water-soluble chitin in water/ethyl acetate. The polymerization proceeded quite smoothly, and both the conversion and grafting efficiency were very high owing to the homogeneous polymerization conditions which became feasible by making use of the water-soluble characteristic of the partially deacetylated chitin. The results of solubility tests, infrared spectroscopy, and X-ray analysis of the copolymers were largely dependent on the side-chain length, and influence of  $\alpha$ -helix formation by the side chains was evident. (Edited author abstract) 14 refs.

**Association**

**083429 AFFINITY INTERACTIONS BETWEEN AGAROSE AND  $\beta$ -1,4-GLYCANS: A MODEL FOR POLYSACCHARIDE ASSOCIATIONS IN ALGAL CELL WALLS.** This paper reviews the extensive and previously unpublished work on the interactions between agarose and 1,4-linked  $\beta$ -D-glycans carried out at Unilever Research, Colworth Laboratory, UK. The effect of the following variables is discussed: galactose content of galactomannans; substitution patterns in the agarose molecule; structural variations in the 1,4- $\beta$ -D-glycan main chain; and molecular size of the 1,4- $\beta$ -D-glycans. In general, the higher the level of galactose substitution in the galactomannan the lower the extent of interaction with agarose. Evidence is presented, however, which indicates that the fine structural distribution of galactose along the galactomannan molecule is also an important determinant for the co-gelling interaction. (Edited author abstract) 59 refs.

**083430 POTENTIAL FOR INDUSTRIAL POLYSACCHARIDES FROM ANAEROBES.** Most bacteria that have been investigated or used for commercial production of polysaccharides are either aerobic or facultatively anaerobic. Aerobic growth results in high substrate conversions, but the increase in viscosity associated with polysaccharide production increases energy requirements for agitation and aeration. Use of anaerobic bacteria, which do not require oxygen and therefore do not need aeration, would therefore significantly decrease the cost of fermentation. In this discussion the authors describe the concepts and possible advantages of producing polysaccharides by anaerobic fermentation. 31 refs.

## Chemical Reactions

**083432 NEW APPROACH TO DEXTRAN DERIVATIVES WITH PENDENT ALDEHYDE GROUPS.** Polysaccharide derivatives containing aldehyde groups can be prepared easily via partial periodate oxidation of the parent polymers. These polyaldehydes have been used as intermediates in the preparation of immobilized enzymes and macromolecular drug derivatives. Soluble dextran derivatives containing aldehyde side groups were prepared by reacting 4-nitrophenyl carbonate ester of dextran with 2, 3-dihydroxypropylamine and subsequent selective periodate oxidation of the pendent diol groups. The hydrolytic stability of the polyaldehyde in acidic medium was comparable with that of unmodified dextran and superior to that of polyaldehydes obtained via partial periodate oxidation of dextran. (Edited author abstract) 15 refs.

## Chromatographic Analysis

**083433 QUANTITATIVE BRANCHING OF LINEAR AND BRANCHED POLYSACCHARIDE MIXTURES BY SIZE EXCLUSION CHROMATOGRAPHY AND ON-LINE LOW-ANGLE LASER LIGHT SCATTERING DETECTION.** The quantitative branching characterization of polysaccharide via size exclusion chromatography (SEC) and on-line low-angle laser light scattering (LALLS) detection is presented from both theoretical arguments as well as direct experimental evidence. The two measurable branching parameters of a sample mixture have been related theoretically to the mixture's composition. There exist linear relationships between  $g_{v(m)}$  and  $W_{b,v}$  (the mass fraction of branched component in mixture) as well as between  $g_{v(m)}^{-1}$  and  $W_{b,v}$ . The latter correlation has been demonstrated experimentally employing a combined SEC/LALLS technique, and displays excellent agreement with the theoretical predictions. Furthermore, this polymer branching characterization method has been applied to study enzymatic starch hydrolysis products. (Edited author abstract) 23 refs.

**083434 CAPILLARY HYDRODYNAMIC CHROMATOGRAPHY OF POLYSACCHARIDES, SCHIZOPHYLLAN, AND XANTHAN.** Capillary hydrodynamic chromatography (c-HDC) of schizophyllan (Sz, unfractionated,  $M_w \approx 250 \times 10^4$ ) and xanthan (Xa, unfractionated,  $M_w \approx 220 \times 10^4$ ) is reported. Pullulan samples ( $M_w = 84.6 \times 10^4$  and  $43.5 \times 10^4$ ) were chromatographed as a reference material. No peak separation from low marker molecules was obtained for the samples. From chromatographic peaks, the effective diameters  $R_{he}$  of Sz and Xa molecules in solution were obtained using polystyrene latex calibration. Intrinsic viscosity and molecular weight data for these polysaccharides gave hydrodynamic volumes and resulting diameters of the molecules,  $R_h$ , in solution by the Flory-Fox equation. (Edited author abstract) In Japanese. 19 refs.

**083435 CHARACTERIZATION OF THE SACCHARIDE COMPOSITION OF HETEROPOLYSACCHARIDES BY PYROLYSIS-CAPILLARY GAS CHROMATOGRAPHY-MASS SPECTROMETRY.** The saccharide composition of a number of heteropolysac-

charides has been successfully characterized by pyrolysis-gas chromatography. In addition, small residues of carbohydrate impurities in samples can be easily identified. The success of pyrolysis-gas chromatography to differentiate among carbohydrates was established by previous studies which found that rapid pyrolysis initiates glycosidic cleavage of saccharide units through transglycosylation thereby forming intact fragments which retain the stereoconfiguration of the saccharide, i.e., anhydro sugars. The high molecular weight product mixtures are resolved on a proper capillary column and the individual anhydro sugars identified by mass spectrometry. (Edited author abstract) 7 refs.

## Crosslinking

**083436 COMPARISON OF GALACTOMANNAN CROSSLINKING WITH ORGANOTITANATES AND BORATES.** Water-soluble polymers crosslinked with metal ions form stable gels that are used in oil and gas production processes. We present an investigation of the chemistry of the binding between guar galactomannans and both borates and titanates using NMR and dynamic light scattering. The two monosaccharides comprising guar - methyl- $\beta$ -D-galactopyranoside and methyl- $\alpha$ -D-mannopyranoside - have been studied as model compounds. High resolution  $^{13}$  CNMR detected complexation of the sugars with borate but displayed no sign of complexation with either of the two titanates even at high titanate concentrations. Dynamic light scattering studies demonstrated the existence of colloidal titanium dioxide particles for both titanate crosslinkers. Data are presented following the growth of these particles with time as a function of pH and salt concentration. The observed particle growth kinetics explains the observed sensitivity of the guar gelation process to these variables. (Edited author abstract) 39 refs.

## Degradation

**083437 ENZYMIC DEGRADATION OF ISOLATED PECTIC SUBSTANCES AND CELL WALL FROM PULP OF GRAPE BERRIES.** Pectic substances sequentially extracted with water (WSP), oxalate (OX), acid (HP) and alkali (OHP) from an alcohol-insoluble residue (AIR) from pulp of grape berries, and further purified, were degraded with two pectic enzymes, namely endopolygalacturonase (endopg) and endopectinylase (endopel). Degradation products were fractionated by gel permeation chromatography (Bio-gel P2, Sephadex G100, Sepharose CL 6B) or by ion-exchange chromatography (DEAE-Sephacel). The results suggest that pectic substances from grape berries are constituted of 'smooth' homogalacturonan areas, interspersed with very densely branched 'hairy' regions where neutral sugar side-chains are located. WSP on one hand and HP, OXP, OHP on the other hand were differentiated by their side-chain length. Treatment of AIR previously extracted with water and oxalate by endopel are reported and degradation products are compared with HP 'hairy' fragments. (Author abstract) 25 refs.

## Extraction

**083438 EXTRACTION AND CHARACTERIZATION OF PECTIC SUBSTANCES FROM PULP OF GRAPE BERRIES.** Pectic substances were successively extracted from the alcohol-insoluble residue (AIR) of the pulp of grape berries, by water (WSP), oxalate (OX), hot dilute HCl (HP) and cold dilute NaOH (OHP). Pectins (WSP, OXP, HP) were purified by ion-exchange chroma-

tography (DEAE-Sephacel) or precipitation with cupric ions (OHP). Total pectic substances represent 20.8% (w/w) of the AIR, WSP and HP being the main components (6% and 12% of the AIR, respectively). An alternative to oxalate extraction of the water-insoluble pectin was extraction with NaCl solutions of increasing concentrations, which had released small amounts of pectins. Each of the fractions contained mainly galacturonic acid, arabinose and galactose, lower amounts of rhamnose and xylose, and minor amounts of glucose and mannose. Ion-exchange chromatography was performed on DEAE-Sephacel,  $M_w$  distribution was checked by gel permeation on Sepharose CL-2B, and  $M_n$  was determined as well as degrees of methylesterification (DM), acetylation (DA), and protein content. (Author abstract) 40 refs.

## Fermentation

**083439 COOPERATIVE BINDING OF SUCROSE IN XANTHAN GUM SOLUTIONS.** In the xanthan gum fermentation mass transfer mechanisms are complex due to the high viscosity of the broth. Diffusional mass transfer becomes very important in transport of solutes such as oxygen and sucrose in the polysaccharide solution. Nevertheless, this process can be affected by the interactions between macromolecule and solute. The present study was designed to determine if xanthan gum interacts with sucrose. The data show that xanthan gum in solution possesses two interaction sites for sucrose. These interactions are adequately described by a cooperative binding model. Changes in ionic strength and pH did not affect either the number of sites or type of interaction. (Author abstract) 22 refs.

## Filtration

**083441 FILTRABILITE DE SOLUTIONS DE POLYSACCHARIDES EN PRESENCE D'ADDITIFS RESULTATS PRELIMINAIRES.** [Filterability of Polysaccharide Solutions in the Presence of Additives. Preliminary Results]. Aqueous solutions of polysaccharides of biochemical origin contain microgels, i.e. aggregates created by the association of several polymer molecules which have a harmful influence on filterability. The author studied how this property evolves as a function of various factors (mechanical shear, addition of reagents). The amplitude of the dissolution effect of aggregates exerted by nonionic surfactants, polyoxyethylenes and anionic surfactants brings about improvement in the filterability of solutions while leaving their viscosities practically intact. (Edited author abstract) 26 refs. In French.

## Molecular Structure

**083444 WATER-SOLUBLE SULFATED POLYSACCHARIDES FROM THE RED SEAWEED CHAETANGIUM FASTIGIATUM. ANALYSIS OF THE SYSTEM AND THE STRUCTURES OF THE  $\alpha$ -D-(1 $\rightarrow$ 3)-LINKED MANNANS.** The water-soluble polysaccharides from *Chaetangium fastigiatum* were fractionated with cetrimide. The complexed material was subjected to fractional solubilization in solutions of increasing sodium chloride concentration and seven fractions were separated and analyzed. Two of the fractions were subjected to methylation and desulfation-methylation analyses. The results indicate that this seaweed contains a system of sulfated polysaccharides consisting in part of a galactan and an  $\alpha$ -D-(1 $\rightarrow$ 3)-linked mannan, 2- and 6-sulfated, and having single stubs of  $\beta$ -(1 $\rightarrow$ 2)-linked D-xylose. Composition dispersity of the mannan is produced by variation of the amount and disposition of the sulfate groups and of the content of the xylose side-chains. (Author abstract) 29 refs.

Matulewicz, M.C. (Univ de Buenos Aires, Buenos Aires, Argent); Cerezo, A.S. *Carbohydr Polym* v 7 n 2 1987 p 121-132.

**083445 HELICAL STRUCTURE OF  $\beta$ (1-3) XYLAN AND THE WATER MEDIATED HYDROGEN BONDING SCHEMES.** A six-fold intertwined triple helical structure for the polysaccharide  $\beta$ (1-3) xylan was generated with the axial advance of 0.306 nm per residue. A stereochemically possible site for the water molecule has been determined and water mediated intrachain and interchain hydrogen bond schemes are possible for the right-handed triple helical structure, whereas only interchain hydrogen bonding appears plausible in the left-handed triple helical structure. The water mediated hydrogen bond is almost linear. X-ray refinement using a Linked-Atom Least-Squares (LALS) procedure has enabled determination of the orientation of the molecule in the hexagonal unit cell, the position of the water molecules and a reliability index,  $R$ , of 0.35. The refined model in this study confirms the original chirality of an earlier model but differs in the water mediated hydrogen bonding scheme. (Edited author abstract) 15 refs.

**083446 STRUCTURAL CHARACTERIZATION OF A TOBACCO RHAMNOLACTURONAN.** A rhamnogalacturonan, extracted with hot water from the aqueous ethanol insoluble residue of flue-cured bright tobacco lamina, was purified by tangential flow ultrafiltration, ion chromatography and gel filtration. It was characterized by

chemical and spectroscopic methods. Fractionation revealed that the rhamnogalacturonan consisted of a series of polysaccharides with different amounts of methyl-esterified galactopyranosyluronic acid residues in the backbone and different amounts of neutral sugar residues. The average degree of polymerization of this tobacco rhamnogalacturonan was estimated to be 400. (Edited author abstract) 34 refs.

## Polymerization

**083448 SELECTIVE RING-OPENING POLYMERIZATION OF DI-O-T-BUTYLDIMETHYLSILYLATED AND DI-O-P-BROMOBENZYLATED 1,4-ANHYDRO- $\alpha$ -L-ARABINOPYRANOSIDES AND STRUCTURAL ANALYSIS OF FREE ARABINANS.** The authors report herein studies of ring-opening polymerization of 1,4-anhydro-2,3-di-O-t-butylidimethylsilyl- $\alpha$ -L-arabinopyranose (ADSA) and 1,4-anhydro-2,3-di-O-p-bromobenzyl- $\alpha$ -L-arabinopyranose (ADBA) by cationic initiation in methylene chloride. Polymerization of ADSA using phosphorus pentafluoride as initiator at  $-60^\circ\text{C}$  gave stereoregular (1 $\rightarrow$ 5)- $\alpha$ -L-arabinofuranan derivatives in 85% yield. Polymerization of ADBA with various Lewis acids afforded slightly less stereoregular polymers ( $\alpha$ -content 90%) under optimum conditions. The polymer structure was characterized by  $^{13}\text{C}$  NMR spectroscopy, specific rotation, and the methylation analysis using GC-MS spectroscopy. (Edited author abstract) 13 refs.

## Reviews

**083449 MICROBIAL POLYSACCHARIDES CONTAINING 6-DEOXY Sugars.** Microorganisms producing polysaccharides rich in 6-deoxysugars are widely distributed among bacteria, algae and fungi isolated from different environments and having different metabolic capabilities. Culture conditions leading to the screening of microorganisms producing these polysaccharides as well as parameters promoting their production necessitated the use of media containing high carbon-nitrogen ratios. Methods for extracting polysaccharides and for measuring their 6-deoxysugars content are either colorimetric or required the use of analytical chromatography. Successful purification procedures leading to pure 6-deoxysugars included ion-exchange chromatography. Among the different applications of these polysaccharides is their use as substrates in the chemical synthesis of flavoring agents. (Author abstract) 115 refs.

**083451 SOLUTION PROPERTIES OF PECTIN POLYSACCHARIDES. I - AQUEOUS SIZE EXCLUSION CHROMATOGRAPHY OF FLAX PECTINS.** Crude pectin from green flax was fractionated on Sephacryl S200 in 1 M NaCl. The fractions obtained were characterized by measuring the anhydrogalacturonic acid content, the degree of esterification (DE), the intrinsic viscosity and the molecular weight  $M_w$ . Lower viscosities are found compared with pectins from other plant sources and a relationship exists between the DE and the molecular size of pectins. Mark-Houwink relationship is observed to depend on the method used for clarification of solutions before measuring  $M_w$ , due to the presence of small amount of high  $M_w$  particles which can considerably distort the light-scattering data without affecting the viscosity values. (Edited author abstract) 31 refs.

Hourdet, Dominique (CNRS, Mont St. Aignan, Fr); Muller, Guy. *Carbohydr Polym* v 7 n 4 1987 p 301-312.

**083452 GELATION OF GELLAN GUM.** The microbial polysaccharide, gellan gum, was studied in aqueous solution and in the gel state by osmometry, viscometry, light scattering, polarimetry and NMR and by measurements of gel strength and cation-exchange selectivity. In solutions of the tetramethylammonium (TMA) salt of the polymer, increasing concentrations of TMA induced contraction, ordering, and association of the chains, as revealed by viscometry and changes in optical rotation. Chain ordering occurred at ionic strengths between 0.005 and 0.5 (M), and light scattering indicated an elongated chain structure in 0.025 M TMA. Gelation was dependent upon both ionic strength and the identity of the cation. Measurements of optical rotation and NMR spectroscopy indicated that chain association and gelation were related phenomena. The results are interpreted as indicating that gelation occurs in two steps, namely, chain ordering and chain association. (Edited author abstract) 28 refs.

Grasdalen, Hans (Univ of Trondheim, Trondheim, Norw); Smidsrod, Olav. *Carbohydr Polym* v 7 n 5 1987 p 371-393.

**083453 LIGHT SCATTERING STUDIES OF SOLUTIONS OF THE BACTERIAL POLYSACCHARIDE (XM6) ELABORATED BY ENTEROBACTER (NCIB 11870).** Light scattering studies have been made on solutions of the sodium and tetra-methyl ammonium salts of the anionic heteropolysaccharide XM6. The polymers may be modeled as stiff wormlike chains. In dilute solution no conformational change was observed upon increasing the ionic strength. Models for gelation at higher polymer concentration are discussed. The measured mass per unit length of the polymer favors an ordered helical conformation and a gelation mechanism involving association and possibly crystallization of segments of the helical chains. (Author abstract) 14 refs.

Chapman, H.D. (AFRC Inst of Food Research, Norwich, Engl); Chilvers, G.R.; Morris, V.J. *Carbohydr Polym* v 7 n 6 1987 p 449-459.

**083454 CONTROLLED GELATION OF XANTHAN BY TRIVALENT CHROMIC IONS.** Addition of trivalent chromic ions to xanthan solutions gives rise to gel formation. The dynamic shear storage and loss moduli

(0.01–10 rad/s) of xanthan solutions with polymer concentrations ranging from 1 to 7 mg/ml and  $\text{Cr}^{3+}$  concentrations ranging from 0 to 50 mM have been studied. It is found that the rate of gel formation is strongly dependent on the  $\text{Cr}^{3+}$  concentration, but to a much smaller extent on the xanthan concentration. The gelation time is less than 1 h for 50  $\mu\text{M}$   $\text{Cr}^{3+}$  and about 40 h for 2 mM  $\text{Cr}^{3+}$ . It is found that the minimum  $\text{Cr}^{3+}$  concentration needed to give gelation of 1–7 mg/ml xanthan is 1–2 mM. Xanthan, and highly viscous polymer solutions in general, are used to improve the sweep efficiency in polymer-or surfactant-flooding or, in a crosslinked state, as a rock-permeability modifying agent to avoid water-channeling in heterogeneous reservoirs. (Edited author abstract) 16 Refs.

## Spectroscopic Analysis

**083456 EFFECTS OF SEASONS ON THE CHEMICAL STRUCTURE AND GEL STRENGTH OF (GRACILIARACEAE, RHODOPHYTA).** The seasonal effects on the chemical structure and rheological properties of *Gracilaria pseudoverrucosa* agar have been investigated using a sequential solvent extraction,  $^{13}\text{C}$  NMR and infrared spectroscopy, and gel strength measurements. The results showed that agar enriched in precursor to the agarobiose repeat unit were obtained from algae collected in summer. In contrast, algae collected in winter contained agar molecules richer in alkali-stable sulfate groups attributed in part to d-galactose-4-sulfate. (Edited author abstract) 48 Refs.

Lahaye, M. (McGill Univ, Montreal, Que, Can); Yaphe, W. *Carbohydr Polym* v 8 n 4 1988 p 285–301.

**083457 PYROLYSIS-MASS SPECTROMETRY OF NATURAL GUMS, RESINS, AND WAXES AND ITS USE FOR DETECTING SUCH MATERIALS IN ANCIENT EGYPTIAN MUMMY CASES (CARTONNAGES).** Pyrolysis-mass spectrometry (Py-MS) has been applied to the study of some ancient Egyptian mummy cases (cartonnages). Samples of organic materials, used in the construction of these objects, have been collected from cartonnages housed in various museums in Europe. Fifty samples were examined by Py-MS and the pyrograms obtained were compared with those of some 70 modern natural gums, resins and waxes. The technique permitted a classification of about half of the ancient adhesives; and polysaccharide gums, waxes and rosins have been detected in samples from objects some 2000 to 4000 years old. (Author abstract) 3 Refs.

## Stability

**083458 THERMAL STABILITY AND CHAIN CONFORMATIONAL STUDIES OF XANTHAN AT DIFFERENT IONIC STRENGTHS.** The aim of the present study was to determine the influence of the ionic strength on the thermal stability of xanthan, i.e. xanthan

resistance to chain breaking at high temperatures. Xanthan solutions of various ionic strengths were kept at 80, 90 and 95°C for periods up to 95 h. The thermal stability was determined by measuring the intrinsic viscosity after the heating periods. The experiments showed a critical ionic strength for the thermal stability of xanthan between 10 and 100 mM NaCl or KCl in this temperature range. The transition temperature ( $T_m$ ) of xanthan was determined by NMR and optical rotation measurements. (Edited author abstract) 33 Refs.

## Synthesis See Also MONOMERS—Polymerization.

**083459 SELECTIVE SYNTHESIS OF POLYSACCHARIDE MACROMERS BY RING-OPENING POLYMERIZATION OF ANHYDRO SUGAR.** Two kinds of stereoregular polysaccharide macromers were prepared by cationic ring-opening polymerization of a 1,4-anhydro sugar. 1,4-Anhydro-2,3-bis(O-tert-butyl-dimethylsilyl)- $\alpha$ -D-ribofuranose was polymerized by acryloyl (or methacryloyl) chloride-silver hexafluorophosphate or silver hexafluoroantimonate complex catalyst to afford (1 $\rightarrow$ 5)- $\alpha$ -D-ribofuranan macromer or (1 $\rightarrow$ 4)- $\beta$ -D-ribofuranan macromer bearing an acryloyl (or methacryloyl) terminal group. The macromer was radically polymerized and copolymerized with methyl methacrylate. Desilylation of the copolymer gave polyribose-grafted poly(methyl methacrylate). The mechanism of the selective ring-opening polymerization was discussed from the viewpoint of the roles of the silyl group, the carbenium ion, and the gegenanion. (Author abstract) 23 Refs.

**083462 WEIGHTED INTRINSIC VISCOSITY RELATIONSHIPS FOR POLYSACCHARIDE MIXTURES IN DILUTE AQUEOUS SOLUTIONS.** The weighted intrinsic viscosities of polysaccharide mixtures in dilute aqueous solutions have been studied. The purpose of this investigation is to demonstrate that average intrinsic viscosities would scale with the weight fractions of the individual components for polysaccharide mixtures in 0.5N NaOH. The polysaccharides examined in this study were composed of polymers differing in their molecular weights, degree of branching, and bond linkages. Excellent agreement between theory and experiment was observed for the three different mixture polymer systems examined. This observation validates certain aspects of proposed theoretical treatments which employ this fundamental assumption and allows for further advances in experimental analytical developments of water-soluble polymer systems. (Edited author abstract) 19 Refs.

Weaver, L. (Worcester Polytechnic Inst, Worcester, MA, USA); Rollings, J.E. *J Appl Polym Sci* v 35 n 6 May 5 1988 p 1631–1637.

**083463 XANTHAN/CAROB INTERACTIONS AT VERY LOW CONCENTRATION.** Xanthan/carob interactions at very low concentration have been studied by viscosity measurements at 25°C and in 0.1 M NaCl. The existence of a weak network structure, exhibiting thixotropic behavior, has been shown, down to reduced concentrations  $C[\eta]$  much lower than that corresponding to coil overlap. Maximum synergistic effects are observed for a xanthan/carob (X/C) ratio of 5.5/4.5. The formation of the network is dependent on the aging time, and, for very dilute systems, a very low shear rate is necessary to observe a transitory network. (Edited author abstract) 41 Refs.

**083464 STABILITY ANALYSIS OF POLYMERIZATION IN CONTINUOUS, STIRRED-TANK REACTORS.** A large number of commercially available polymers such as polystyrene, HIPS (high-impact polystyrene), polyvinyl chloride, and polymethyl methacrylate are produced in continuous free-radical bulk polymerization processes. Back-mixed reactors are frequently employed which involve either a continuous stirred-tank reactor (CSTR) or a plug-flow reactor (PFR) with recycle. Inherent in such back-mixed reactors is the potential for multiple steady states (MSS). There are two graphical procedures for determining the steady-state operating point and the potential for multiplicity (MSS): one for the isothermal CSTR and the other for the nonisothermal CSTR. 26 Refs.

**083465 PREPARATION OF THREE-ARMED STAR POLYSTYRENE BY REACTION OF PREPOLYMER HAVING A TERMINAL FUNCTIONAL GROUP WITH TRIISOCYANATE.** Polystyrene prepolymers having hydroxyl or amino groups at their ends were prepared by anionic polymerization techniques. The linking reactions of these prepolymers with triisocyanate

derived from lysine were carried out under various conditions and their efficiencies of conversion to three-armed star polymers were determined by GPC measurements. The reaction of the prepolymer having an -OH group with triisocyanate under catalysis of tri-*n*-butyltin oxide as well as the direct reaction of the intermediate polystyryl anion with triisocyanate was found to be most effective for preparation of star polystyrene having three arms. The star polymer thus prepared was successfully isolated by fractionation procedures after treating the reaction mixture with reactive polystyrene gels containing sulfonyl chloride or isothiocyanate groups. The number of arms of the isolated star polymer was confirmed to be virtually three by the ratio of the number-average molecular weight of the star polymer to that of the corresponding prepolymer. (Author abstract) 23 refs.

**083466 SANS STUDY OF PARTICLE NUCLEATION IN EMULSION POLYMERIZATION.** We describe the use of small-angle neutron scattering (SANS) to measure the average radius of polystyrene particles in the early stages of emulsion polymerization. Polymerization was started by placing monomer in contact with an aqueous polyacrylamide gel containing initiator, in the absence of surfactant. Reaction was allowed to occur for 12, 24, and 48 h, and slices were removed from the gels in each system at various distances (of order 10 mm) from the interface. SANS measurements on these slices showed the presence of particles of radius  $6 \pm 1$  nm. These experiments show that, in these systems, one can halt the growth (by propagation and coagulation) of very small colloidal particles for a sufficiently long time to measure physical properties such as the amount of monomer imbibed at equilibrium swelling, surface charge, etc. (Author abstract) 9 refs.

**083467 STUDY OF END GROUPS IN OLIGO- AND POLYSTYRENE PREPARED USING AZOBIS-ISOBUTYRONITRILE.** Oligo- and polystyrene were prepared at 60°C in the presence of azobisisobutyronitrile. The species in the given oligomer and polymer was estimated by  $^{13}\text{C}$  and  $^1\text{H}$  n.m.r. It is shown that primary radical termination is important when the initiator concentration is high and the monomer concentration is low, and that styrene radicals terminate mainly by combination. (Author abstract) 7 refs.

**083468 INTERACTIONS BETWEEN POLYSTYRENE LATEX SPHERES AND A SEMIFLEXIBLE POLYMER, HYDROXYPROPYLCELLULOSE.** We explore stiff polymer/particle interactions from both static and dynamic viewpoints. The nonionic polymer hydroxypropylcellulose (HPC) was chosen to focus on the effects of polymer stiffness in the absence of electrostatic interaction. The persistence length of HPC is about 100 Å, similar to that of many other cellulose derivatives. HPC is quite stiff enough to form lyotropic liquid crystals, even in the absence of any external alignment. In this regard, HPC is stiffer than many polymers designed to be thermotropic liquid crystals, which often only display stir opalescence in solution. Thus, there is a clear physical distinction between HPC and typical random coil polymers. We may say that HPC is 'semiflexible'. 41 refs.

**083469 IMPROVED PROCESS FOR THE PREPARATION OF HIGH-IMPACT POLYSTYRENE.** A

description is given of an improved process for the preparation of high-impact polystyrene. The improved design of the reactor and its stirrer with variable controlled speed drive resulted not only in lowering the time and temperature profile of polymerization but also yielded a better quality product. The mechanism of particle formation and other phenomena occurring during the polymerization of a solution of polybutadiene in styrene is also discussed.

## Ablation

**083470 MASS SPECTROSCOPIC STUDIES OF THE ArF-LASER PHOTOABLATION OF POLYSTYRENE.** We have investigated the photoablation of polystyrene by ArF-laser radiation (193 nm) with respect to the chemical nature and energy distribution of ejected molecular species. A novel analytical technique combining photoionization by vacuum-ultraviolet laser radiation at 118.4 nm with time-of-flight mass spectrometry has been employed. At near threshold fluences above  $15\text{mJcm}^{-2}$  the main neutral photoablation product is the styrene monomer. Using direct time resolved detection the kinetic energy distribution of the product molecules has been determined, its peaks at about 0.7 eV. (Edited author abstract) 16 refs.

Feldmann, D. (Univ Bielefeld, Bielefeld, West Ger); Kutzner, J.; Laukemper, J.; MacRobert, S.; Welge, K.H. *Appl Phys B* v B44 n 2 Oct 1987 p 81-85.

**083471 TIME-RESOLVED EXPERIMENTS ON THE PHOTOABLATION OF POLYSTYRENE AND PMMA BY ArF-LASER RADIATION.** The photoablation of polystyrene (PS) and polymethylmethacrylate (PMMA) was studied in real-time during the uv laser pulse at 193 nm. The transmission and total reflection of thin polymer layers on quartz glass substrates was measured time-resolved. From the results for the strongly absorbing PS it can be concluded that the emission of material starts within the first few nanoseconds of the laser pulse. Photoablation of PMMA, which is a relatively weak absorber at 193 nm, is accompanied by strong modifications of the transmission by the first several ten laser pulses. (Author abstract) 12 refs.

## Acoustic Wave Effects

**083472 EXPERIMENTAL DETERMINATION OF RESONANT FORWARD SCATTERING OF SOLID INCLUSIONS IN A FLUID.** Continuous growth over recent years of the utilization of heterogeneous materials has introduced the problem of characterization. Variations of attenuation with frequency and the physical characteristics of the media are major problems. A first approach is obtained using the classic models based on the scattering cross-section. We present results obtained for the scattering cross-section of a polystyrene obstacle immersed in water. We have concentrated on the design and realization of an experimental set-up and the results show good agreement with theory. (Edited author abstract) 26 refs.

## Additives

**083473 METHYL METHACRYLATE GRAFTED RUBBERS AS IMPACT MODIFIERS FOR STYRENIC POLYMERS.** The use of methyl methacrylate-grafted latex rubber (MMA-g) particles has been studied for the impact toughening of styrenic matrix polymers. It was found that the addition of MMA-g to mass made acrylonitrile-butadiene-styrene (ABS) and

high-impact polystyrene (HIPS) significantly increases their impact strength. While the effectiveness of MMA-g for enhancing the toughness of ABS was not surprising because of the miscibility of the styrene-acrylonitrile copolymer matrix and the poly(methyl methacrylate) graft, its effectiveness in HIPS was unexpected. Possible reasons for the broad effectiveness of the small methyl methacrylate-grafted rubber particles in the various systems are discussed. (Edited author abstract) 24 refs.

## Adsorption

**083474 EFFECT OF ELONGATIONAL FLOW ON POLYMER ADSORPTION.** The adsorption and desorption of polystyrene (PS) from cyclohexane at 34.8°C (θ temperature) on a chrome mirror has been studied by using ellipsometry. Static adsorption measurements give adsorbed layer thickness and adsorbed and desorption was studied by directing a jet of polymer solution or solvent perpendicular to the mirror surface, to produce an elongational velocity field at the stagnation point on the surface. For a  $10^7$  Mw PS adsorbed under strong elongational flow conditions, the adsorbed layer was an order of magnitude thinner than a layer adsorbed under quiescent conditions and the polymer concentration in the layer adsorbed under elongational flow was 3.4 times higher. (Edited author abstract) 14 refs.

**083475 POLYMER MONOLAYERS PREPARED BY THE SPONTANEOUS ADSORPTION OF SULFUR-FUNCTIONALIZED POLYSTYRENE ON GOLD SURFACES.** Polystyrene containing one terminal thiol group (PS-SH) and styrene-propylene sulfide block copolymers (PS-PPS) were allowed to adsorb on evaporated gold films supported on glass. The resulting supported films were characterized by X-ray photoelectron spectroscopy, external reflectance infrared spectroscopy, and scintillation counting of radioisotope-labeled polymers. The polymers adsorb rapidly and irreversibly, and the polymer monolayers can be washed with fresh solvent without desorption. The effects of molecular weight, concentration, and solvent power on adsorbance were determined for PS-SH. The effect of propylene sulfide block size for a series of PS-PPS copolymers on the number of adsorbed chains was determined. (Author abstract) 25 refs.

**083476 THERMODYNAMIC AND KINETIC FACTORS IN ADSORPTION OF POLYMERS ON A PLANE LATTICE.** The rate of formation of an adsorbed polystyrene monolayer onto silica/carbon tetrachloride interfaces is studied by a radioactive tracer method with  $^3\text{H}$ -labeled polymers. The influence of the temperature on the amount of the polymer adsorbed is determined, and the kinetic law of the adsorption is formulated. At low solution concentrations, the polymer adsorbs with a very flattened conformation, and the kinetic parameter of the adsorption process is quantitatively analyzed with use of a mechanism corresponding to a two-dimensional lattice filling. This process may be regarded as a 'solution' process such as the mixing on a molecular scale, which involves, beside surface forces, local conformational changes and entropy of mixing effects. At higher solution concentrations, loops and/or tails emerge from the surface at a very low rate. (Author abstract). 30 Refs.

**083477 EXPANDABLE POLYSTYRENE (EPS).** The economic importance of expandable polystyrene (EPS) can be seen from figures for their consumption in the western world in recent years, which in 1985 passed the 1 million tonnes mark. Of this total, 42% was in Western Europe, 27% in North America, 15% in Japan, and 16% in the remaining countries of the western world. Consumption per capita is noticeably higher where insulating materials are much used, as in the Scandinavian countries. EPS is generally made by suspension polymerization of styrene with simultaneous addition of blowing agents. Other processes are also used, especially in the manufacture of drinking cups, in which expanding ability is conferred by injecting the blowing agent at a later stage. Systems for computer-aided control of the machines, usually in conjunction with a VDU screen or LC display, are now increasingly common. 8 refs.

**083478 ORIENTATION AND RELAXATION IN UNIAXIALLY STRETCHED POLY(O-CHLOROSTYRENE)-POLYSTYRENE BLENDS.** Orientation and relaxation of polymer chains have been analyzed in uniaxially stretched films of poly(o-chlorostyrene) (PoCS) and of compatible PoCS/polystyrene (PS) blends. The intrinsic birefringence of PoCS is derived from fluorescence and birefringence orientation measurements. Further, using Fourier transform infra-red spectroscopy, the authors have determined the angle between the dipole moment vector of some infra-red vibrations of PoCS and the chain axis. The orientation of the benzene ring with respect to the chain axis in oriented PoCS samples is identical to that observed in PS. In PoCS/PS blends, infra-red and birefringence measurements show that chain orientation of both polymers is almost the same and independent of the presence of the second component, in agreement with mechanical relaxation measurements. (Edited author abstract) 23 refs.

**083479 INVESTIGATION OF THE BLEND OF PARTIALLY BROMINATED POLY(2,6-DIMETHYL 1,4-PHENYLENE OXIDE) AND POLYSTYRENE IN THE PRIMARY (GLASS-TO-RUBBER) TRANSITION REGION.** Compatible polymer blends can be used to test critically the viability of the damped Debye lattice (DDL) model of relaxation in the primary (glass-to-rubber) transition region. The model predicts an unusual sharpening of the stress relaxation master curve of a marginally two-dimensional DDL upon dilution with a plasticizer. We have prepared an appropriate two-dimensional DDL by adding modest amounts of partially brominated poly(2,6-dimethyl 1,4-phenylene oxide) to polystyrene to form compatible blends. As predicted by the model, sharpening of the stress relaxation behavior upon dilution was observed for all blend compositions and for all diluents used. However, at higher brominated poly(phenylene oxide) concentrations, the anticipated diluent concentration dependence was not always observed and the sharpening of the stress relaxation behavior was less than expected. (Edited author abstract) 18 refs.

**083480 PHASE BEHAVIOR FOR BLENDS OF**

**STYRENE CONTAINING TRIBLOCK COPOLYMERS WITH POLY(2,6-DIMETHYL-1,4-PHENYLENE OXIDE).** The extent to which the styrene end-blocks of three commercially available triblock copolymers can mix with a particular poly(2,6-dimethyl-1,4-phenylene oxide) ( $M_n=22,600$  and  $M_w=34,000$ ) or PPO has been examined by investigation of the glass transition behavior of the PPO and polystyrene (PS) portions of the blends using differential scanning calorimetry. Each block copolymer has a butadiene-based mid-block which was hydrogenated for two of these materials, but not the third. The three copolymers differ substantially in overall molecular weight and in molecular weight of the blocks. For blends of homopolymer PS with styrene-based block copolymers, the two-phase behavior of the glassy portion can be readily explained by entropic considerations. For the present case, the favorable enthalpic contribution for mixing PPO and PS is an additional factor which seems to influence the restrictions on molecular weight for complete mixing; however, additional work is needed to develop a more quantitative assessment of this new issue. (Edited author abstract) 33 refs.

**083481 GAS SORPTION AND TRANSPORT IN MISCIBLE BLENDS OF TETRAMETHYL BISPHENOL-A POLYCARBONATE AND POLYSTYRENE.** The permeability coefficients for He, O<sub>2</sub>, N<sub>2</sub>, CH<sub>4</sub>, and CO<sub>2</sub> in miscible blends of polystyrene (PS) and tetramethyl bisphenol-A polycarbonate (TMPC) at 35°C and 1 atm driving pressure are reported. Sorption isotherms for CO<sub>2</sub> and CH<sub>4</sub> are also presented. The isotherms were fitted to the dual sorption model. The Langmuir capacity factor was found to follow an earlier correlation based on unrelaxed volume. For each gas, the permeability was found to go through a minimum when plotted against blend composition. This behavior is primarily the result of the volume change on mixing observed for this system. The attractive interaction between TMPC and PS is relatively strong as indicated by density and solubility data. The value of the binary interaction parameter was found to be of the same magnitude as that for poly(phenylene oxide) (PPO)-polystyrene (PS) blends. Considering the similarity of structure between PPO and TMPC, it is concluded that similar phenyl-phenyl interactions and conformation changes on blending may prevail in TMPC/PS blends. (Author abstract) 37 refs.

**083482 COUPLING OF REACTIVE POLYSTYRENE AND POLYETHYLENE IN MELTS.** Polystyrene (OPS) having oxazoline groups and polyethylene (CPE) having carboxyl groups were melt blended in a Rheomix mixer. The effects of composition on the torque, thermal transitions, solubility and phase structure of these resulting polymer alloys were investigated. Differential scanning calorimetry (d.s.c.) and scanning electron microscopy (SEM) data on these alloys is compared with the corresponding melt blends of the non-reactive polymers. The torque-time relationship, phase structure and thermal properties of these polymer alloys were found to be very different from the non-reactive blends, and this was more so in an alloy with 40% CPE. (Edited author abstract) 15 refs.

**083483 CRYSTALLIZATION BEHAVIOUR OF POLY(PHENYLENE SULPHIDE)/POLYSTYRENE BLEND.** The crystallinity of poly(phenylene sulphide) (PPS) blended with polystyrene has been investigated as a function of composition, annealing time and temperature by an X-ray diffraction technique for samples made by three mixing techniques viz. powder blending, melt blending and solution blending. The method of blending has a pronounced effect on the crystallinity, solution

blending giving the least for a particular composition. The crystallization half time increases while the crystallite size is reduced considerably by the addition of polystyrene to PPS. These findings have been explained on the basis of partial miscibility of the amorphous phases. (Author abstract) 25 refs.

**083484 STUDY OF THE COMPATIBILITY OF BLENDS OF POLYMERS AND COPOLYMERS CONTAINING STYRENE, 4-HYDROXYSTYRENE AND 4-VINYLPYRIDINE.** Differential scanning calorimetry was used to show that poly(4-vinylpyridine) is incompatible with polystyrene but compatible with poly(4-hydroxystyrene) over the entire range of composition. Compatibility between poly(4-vinylpyridine) and styrene-rich copolymers is achieved by introducing into the copolymers reactive groups which are able to complex with poly(4-vinylpyridine) through hydrogen bonding. Similarly, miscibility between poly(4-hydroxystyrene) and polystyrene, which are incompatible over the entire range of composition, is only achieved if polystyrene is modified by incorporation of large amounts of (4-vinylpyridine) units. These results confirm that for such dissimilar polymers compatibility can only be achieved through cumulative interactions of added functionalities. (Edited author abstract) 15 refs.

Vivas de Meftahi, Marina (Univ of Ottawa, Ottawa, Ont, Can); Frechet, Jean M.J. *Polymer* v 29 n 3 Mar 1988 p 477-482.

**083485 TEMPERATURE AND CONCENTRATION DEPENDENCE OF THE INTERACTION PARAMETER IN OLIGOMERIC POLYMER BLENDS FROM SMALL-ANGLE NEUTRON SCATTERING AND CALORIMETRIC MEASUREMENTS.** Small-angle neutron scattering has been used to determine the concentration and temperature dependence of the interaction parameter  $\chi$  in a blend of two polymers. The interaction parameter can be obtained either by analyzing the angular dependence of the scattering in terms of an apparent radius of gyration or by extrapolation of the data to zero scattering angle. The authors present a comparison of these two methods for two blends of oligomeric polystyrene with polybutadiene. The temperature dependence of the interaction parameter has been determined for a blend of oligomeric methoxylated poly(ethylene glycol) with methoxylated poly(propylene glycol) where the latter component contains a percentage of labeled chains. (Edited author abstract) 27 refs.

Tomlins, P.E. (Imperial Coll, London, Engl); Higgins, J.S. *Macromolecules* v 21 n 2 Feb 1988 p 425-432.

**083486 STRUCTURE RELAXATION AFTER TEMPERATURE JUMPS IN HOMOGENEOUS POLYSTYRENE/POLY(STYRENE-10% BROMOSTYRENE) BLENDS.** Concentration fluctuations in polymer blends and their change after a temperature jump were studied by time-dependent small angle X-ray scattering experiments. Measurements were conducted on homogeneous mixtures of polystyrene and a partially brominated derivative. Structure factors in thermal equilibrium show the form given by the random phase approximation. Relaxation occurs on the time scale of minutes and is nonexponential, becoming slower with time. Initial relaxation rates increase with increasing scattering vectors in accordance with theoretical predictions. (Edited author abstract) 9 refs.

**083489 ENTANGLEMENT IN BLENDS OF MONODISPERSE STAR AND LINEAR POLYSTYRENES. 1. DILUTE BLENDS.** Viscoelastic properties of binary blends composed of narrow molecular weight distribution (MWD) 4-arm star polystyrenes (2-chain) of molecular weight (MW)  $M_2$  and narrow MWD linear polystyrenes (1-chain) of  $M_1$  were examined and compared with binary blends of narrow MWD linear polystyrenes of  $M_2$  and  $M_1$ . In these blends the volume fraction  $\phi_2$  of the 2-chain was kept small so that the 2-chains were entangling only with the matrix 1-chains but not with themselves. When the MW of the components of these dilute blends were such that  $M_c < M_1 \ll M_2$ , with  $M_c$  being the characteristic MW, the star 2-chain exhibited Rouse-Ham-like relaxation modes with the (weight average) relaxation time proportional to  $\phi_2^0 M_1^3 M_2^2$  and the compliance proportional to  $\phi_2^{-1} M_1^0 M_2$ . (Edited author abstract). 41 Refs.

## Chlorination

**083496 PHASE TRANSFER CATALYZED CHLORINATION OF POLY(P-METHYLSTYRENE).** Chlorination of the methyl groups of poly(p-methylstyrene) with aqueous sodium hypochlorite and benzyltriethylammonium chloride as catalyst provides a new route to chloromethyl-substituted aromatic polymers. Conversions of up to 20% of methyl to chloromethyl groups were achieved with no detectable formation of dichloromethyl groups. Conversion of up to 73% of methyl to chloromethyl groups occurs with 12% concomitant formation of dichloromethyl groups. The method has been applied to soluble, 1% crosslinked, and 20% crosslinked macroporous polymers. Phase transfer catalyzed chlorination of poly(p-methylstyrene) is much safer than chloromethylation of polystyrene and much less expensive than the use of chloromethylstyrene monomer for preparation of functional derivatives of polystyrene. (Author abstract)

## Chromatographic Analysis

**083497 CHARACTERIZATION OF CHLOROMETHYL-SUBSTITUTED POLYSTYRENE NETWORKS BY HIGH-RESOLUTION PYROLYSIS-GAS CHROMATOGRAPHY.** Three types of chloromethyl-substituted polystyrene networks prepared by different methods are studied by high-resolution pyrolysis-gas chromatography. The methods of introduction of chloromethyl groups are readily identified from the pyrolyzates characteristic of each copolymer. The degree of chloromethyl substitution is also estimated from the changes in the peak intensities of the characteristic pyrolyzates. Additionally, the thermal degradation behavior of these polystyrene networks is studied by thermogravimetric analysis. The pyrolysis-gas chromatography results can be used as a method of quantitative analysis of the amount of chlorine in these chloromethyl-substituted polystyrenes. (Author abstract) 9 refs.

**083498 DYNAMIC HEADSPACE CAPILLARY GAS CHROMATOGRAPHY: A VERSATILE ANALYTICAL TECHNIQUE.** The applicability of dynamic headspace analyses for viscous liquids and solid samples is demonstrated. Some comments on the usefulness of this technique for quantifying volatiles in polymeric matrices are made. Dynamic headspace analysis can easily be applied to viscous liquids and solid samples. Although this paper contains only illustrations based upon polymeric solids, the technique may be applied to all kinds of solid materials. The use of repeated desorption cycles of the same sample gives valuable information on the precision of the quantification of volatiles and/or their formation at the desorption temperature. 5 refs.

## Crack Propagation

**083499 CRAZE GROWTH AND HEALING IN POLYSTYRENE.** The kinetics of craze growth and craze healing were studied by dark-field optical microscopy in monodisperse molecular weight polystyrene (PS) that varied in molecular weight from 88,000 to 1,334,000. The following observations were made.  $G_1$ , the virgin growth rate, decreased rapidly with increasing molecular weight until  $M_n$  approx. 200,000 and then remained constant.  $G_1$  decreased with increasing craze density. The growth rates of approaching craze tips decreased when the craze tips overlapped, and the effect was less for crazes whose parallel growth paths were greater than 40  $\mu$ m apart. Complete craze healing was observed by the comparison of the nucleation times and growth rates,  $G_2$ , of healed individual crazes with the craze kinetics of the virgin sample. Craze healing studies provide insight into both crack healing and fracture of glassy polymers. (Edited author abstract) 37 refs.

**083500 ON SELF-SIMILARITY OF CRACK LAYER.** It is commonly recognized that microdefects (damage) play a significant role in the process of crack formation and growth. An important case is when the density of damage induced by a propagating crack as a response to the stress concentration at the crack tip is much greater than the density of the pre-existing damage. This strongly cooperative phenomenon is modeled by the Crack Layer Theory. In its scope 'crack layer' (CL) is defined as the system consisting of the main crack together with the surrounding damage. The objective of this report is to examine the self-similarity hypothesis for quasistatic CL propagation using polystyrene as a model material. 6 refs.

Botsis, J. (Univ of Illinois at Chicago, Chicago, IL, USA); Kunin, B. *Int J Fract* v 35 n 3 Nov 1987 p R51-R56.

**083501 CRACK AND DAMAGE PROPAGATION IN POLYSTYRENE UNDER FATIGUE LOADING.** Fatigue crack propagation experiments conducted on thin, single edge-notched polystyrene specimens demonstrate that during quasi-static propagation intense crazing surrounds and precedes the crack. The crack and its associated damage constitute a crack layer (CL). Craze accumulation within the zone ahead of the crack tip, i.e. the active zone, takes place prior to crack advance. During crack advance, the shape of the crack tip closely resembles that of the Dugdale-Barenblatt model. The experimental results demonstrate that fracture propagates by the translation, expansion and distortion of the active zone. The critical energy release rate is found to be strongly dependent on loading history. (Edited author abstract) 33 refs.

**083502 COMPARISON OF MINIMAL PRINCIPAL STRESS TRAJECTORIES WITH CRAZE DISTRIBUTION IN AN AMORPHOUS POLYMER.** Analysis of the distribution of surface crazes in the vicinity of a stationary edge crack in a polystyrene (PS) sheet in tension has shown the craze growth occurs along directions parallel to the minor principal stress axis. In this study, a correlation between the principal stress trajectories in the vicinity of notches and crazing patterns in PS under tension loading is established. Tresca's criteria are

used to compare these patterns with the experimentally observed ones. 8 Refs.

Chabaat, M. (Case Western Reserve Univ, Cleveland, OH, USA). *Int J Fract* v 37 n 4 Aug 1988 p R47-R54.

## Crazing

**083503 EFFECT OF ENVIRONMENTAL WATER ON THE CRAZE GROWTH RATE OF ATACTIC POLYSTYRENE.** The effect of water at standard temperature and pressure on the rate of craze growth in polystyrene was studied with an elapsed-time photography method. Water was found to be a mild crazing agent for polystyrene, increasing the craze velocity by somewhat more than an order of magnitude at room temperature. The craze length was found to increase proportional to the square root of time, as is expected for transport-limited solvent crazing. The interface convolution model for craze growth and thickening was found to account well for the stress dependence of the craze front velocity in both the 'dry' and the 'wet' states, and for the total effect of water on the craze velocity. The stress dependence of the craze front velocity implies that craze fibrils grow by surface drawing and that water molecules interact only with the plastically deforming fringing layer of polymer at the craze borders. (Author abstract) 17 refs.

Crosslinking See Also MEMBRANES—Manufacture.

**083504 POLY( $\alpha$ -AMINO ACID)-IMMOBILIZED POLYMER ADSORBENTS FOR OPTICAL RESOLUTION. I. SYNTHESIS, CHARACTERIZATION, AND EVALUATION OF POLY(L-GLUTAMIC ACID) DERIVATIVES-IMMOBILIZED POLYMER ADSORBENTS.** As a novel polymer adsorbent for optical resolution, cross-linked polystyrene gel incorporating poly( $\alpha$ -amino acids) was synthesized. The helicity of the incorporated poly( $\gamma$ -benzyl L-glutamate) (PBLG) was demonstrated by Fourier-transform infrared spectroscopy. The immobilized PBLG (I) was converted to poly(L-glutamic acid) (II) and poly(N<sup>5</sup>-benzyl-L-glutamine) (III). The ability of I-III to resolve DL-mandelic acid was evaluated by liquid chromatography using toluene/dioxane as an eluent. Of the three resins, III resolves the racemate most effectively. In order to clarify the mechanism of chiral recognition, poly(N<sup>5</sup>-benzyl-D-glutamine) and poly(N<sup>4</sup>-benzyl-L-asparagine), with opposite helicity, was incorporated. In contrast to III, these adsorbents demonstrated affinity for the L isomer. This results strongly indicates that the helical structure of the immobilized poly( $\alpha$ -amino acids) is essential for chiral recognition. (Author abstract) 23 refs.

Kiniwa, Hideaki (Mitsubishi Chemical Industries Ltd, Yokohama, Jpn); Nishikaji, Takashi; Ogata, Naoya. *J Polym Sci Part A* v 25 n 10 Oct 1987 p 2689-2698.

**083505 SOLUTION PROPERTIES AND DYNAMIC BULK BEHAVIOR OF INTERMOLECULAR CROSS-LINKED POLYSTYRENE.** Linear polystyrene (PS) molecules were intramolecularly cross-linked with p-bis(chloromethyl)benzene in dilute solution. The resulting 'microgels' were characterized in solution by static and dynamic light scattering, GPC, and viscosity measurements. We find a surprisingly small reduction of the radius of gyration and the hydrodynamic radius even for highly cross-linked PS molecules having molecular weights up to  $5 \times 10^5$  and an average number of  $P_c = 20$  monomer units between cross-links. Dynamic mechanical measurements in samples having  $P_c \geq 10$  yield no change of the plateau modulus in comparison to the linear molecules but a broadening and shift to lower frequencies of the terminal zone if compared with linear PS. Furthermore, we find that the product of the self-diffusion coefficient and the zero-shear viscosity is constant, and the diffusion of PS chains in a matrix of microgels is independent of the cross-link density. Various explanations are discussed, but no decision for a particular model (describing all experimental results) can be made. (Author abstract) 41 refs.

Antonietti, Markus (Univ Mainz, Mainz, West Ger); Sillescu, Hans; Schmidt, Manfred; Schuch, Horst. *Macromolecules* v 21 n 3 Mar 1988 p 736-742.

**083506 CROSSLINKING OF POLYSTYRENE UNDER FRIEDEL-CRAFTS CONDITIONS IN DI-CHLOROETHANE AND CARBON TETRACHLORIDE SOLVENTS THROUGH THE FORMATION OF STRONGLY COLORED POLYMER- $AlCl_3$ -SOLVENT COMPLEXES.** Polystyrene was crosslinked in either 1,2-dichloroethane or carbon tetrachloride in the presence of aluminum chloride. Apparently, the reactions involve Friedel-Crafts substitution of phenyl ring with  $CH_2CH_2Cl$  or  $CCl_3$  groups, which then participate in crosslinking, giving  $CH_2CH_2$  or  $CCl_2$ ,  $CCl$ , and C bridges. In the first stage a charge-transfer complex is formed between  $AlCl_3$ , polystyrene and the solvent. After heating this complex above 35-40°C a rapid formation of HCl inflammable. It decomposes at 400°C without melting. (Author abstract) 15 Refs.

Rabek, Jan F. (Royal Inst of Technology, Stockholm, Sweden); Lucki, Julia. *J Polym Sci Part A* v 26 n 9 Aug 20 1988 p 2537-2551.

## Decomposition

**083507 POLYSTYRENES: A REVIEW OF THE LITERATURE ON THE PRODUCTS OF THERMAL DECOMPOSITION AND TOXICITY.** The current English literature through 1984 on the products of pyrolysis and combustion from polystyrenes and the toxicity of those products is reviewed. Among 57 compounds detected by chemical analyses of the thermal decomposition products produced under various atmospheric conditions (vacuum, inert and oxidative), the main volatile component is the styrene monomer. Evidence is provided that the mass fraction of styrene increases with furnace temperatures at least through 500°C. At 800°C and above, the concentration of styrene decreases. In oxidative atmospheres, carbon monoxide (CO), carbon dioxide (CO<sub>2</sub>) and oxidative hydrocarbons are formed. The concentrations of CO and CO<sub>2</sub> are a function of temperature and combustion conditions, i.e. greater amounts are produced in the flaming than in the non-flaming mode. Eleven different test procedures were used to evaluate the toxicity of the pyrolysis and combustion atmospheres of polystyrenes. The more toxic environments produced under flaming conditions appear to be mainly attributed to CO and CO<sub>2</sub>. (Edited author abstract) 69 refs.

**083508 EFFECTS OF HEAT AND MASS TRANSPORT ON THE RESULTS OF THERMAL DECOMPOSITION STUDIES: PART 2. POLYSTYRENE, POLYTETRAFLUOROETHYLENE AND POLYPROPYLENE.** The thermal decomposition of pure polymer samples was studied at a low heating rate (4°C/min) and with sample masses of 0.3-6 mg in a Perkin-Elmer TGS-2 thermobalance. The various transport effects were distinguished by changing the gas flow from argon to helium, varying the sample mass and geometry and by applying a self-generated atmosphere. Sample masses of 3-6 mg showed marked effects of insufficient heat transfer in a flow of argon. The concentration of the volatile products above the samples did not influence the thermal decomposition. The diffusion problems in the polymer bulk, however, changed the kinetics from first order to zero order in the case of polytetrafluoroethylene, and increased the overall reactions rate of polypropylene. (Edited author abstract) 14 refs.

## Defects

**083509 SIZE AND SHAPE OF THE CRITICAL STRUCTURAL DEFECT IN POLYSTYRENE AND POLYMERS REINFORCED WITH RUBBER.** The effect of a critical structural defect on the strength of polymers under conditions of impact loading is considered. With PS, toughened PS and an ABS plastic, the size and shape of the critical structural defect have been determined using the method proposed previously. The size of the critical structural defect is related to the polymer's supermolecular structure. It is concluded that polymers with a rounded critical structural defect have enhanced sensitivity to artificial surface defects. (Author abstract) 19 refs.

## Deformation

**083510 STORED ENERGY OF COLD WORK IN POLYSTYRENE.** The energy stored in polystyrene after plastic deformation is measured by the differential scanning calorimetry (DSC) technique. Similar to metals, the stored energy increases with plastic straining, first rapidly, and then more slowly, and finally the stored energy seems to approach a saturation value (about 1 cal/gram). By comparing to the plastic work done, the fraction stored ranges from 30 percent after 10 percent compression to 10 percent after 60 percent compression. The fraction is about twice as large as that of copper. The release of stored energy has two distinct parts, one below  $T_g$  and the other above  $T_g$ . (Edited author abstract) 23 Refs.

## Degradation

**083511 STUDY OF SOLID CHAR RESIDUES AFTER THERMAL DEGRADATION OF POLYSTYRENE, PVC AND POLYAMIDE - PART II.** In the course of thermal degradation of polymers complex pyrolytic and thermo-oxidizing processes take place. The products of these complex processes are resistant char residues, the analysis of which can be useful in fire cause investigation. Structural residues of the original polymer remain in the char portion of degraded polymer depending on the temperature and duration of the thermal degradation and the temperature. Elementary analysis and infrared spectroscopy have been used for the identification of char residues. (Edited author abstract) 3 refs.

Sevecok, P. (Mining Univ, Ostrava, Czech); Stuzka, V. *Fire Mater* v 11 n 2 Jun 1987 p 89-93.

**083512 PHOTO-DEGRADATION OF BLENDS OF POLYSTYRENE AND POLY(METHYL METHACRYLATE).** Studies of the photo-degradation of blends of polystyrene (PSt) and poly(methyl methacrylate) (PMMA) were made using ultraviolet (UV) and Fourier transform infrared (FTIR) spectroscopy and viscosity measurements. Optical density around 300 nm increases with the increase in the proportion of the PMMA component in the blend. A similar trend is also seen in the formation of oxygenated products. The number of chain scissions calculated from viscosity measurements also becomes greater as the PMMA component in the blend is increased. It has been found that the degradation of PSt-PMMA blends takes place in the PMMA. Interaction between PSt and PMMA in the component boundary regions has not been observed. (Author abstract) 10 refs.

## Desorption

**083513 POLYMER DESORPTION BY NMR.** In a recent paper, the authors used solid state and high

resolution NMR to look at the rates of adsorption and desorption of polystyrene at the carbon/chloroform interface. The authors found that the adsorption is reversible both when the polymer solution is diluted and when it is concentrated by polymer. In particular, by using deuterated and protonated polymer with the same number of monomers, the authors were able to observe adsorption in the presence of desorption and desorption in the presence of adsorption. The time scales of the results suggest that the time taken for the polymer to be displaced is greater than it is to be incorporated. (Edited author abstract) 1 ref.

## Differential Thermal Analysis

**083514 L'ATD DANS L'IDENTIFICATION DU POLYSTYRENE ET DE SES COPOLYMERES A USAGE ALIMENTAIRE ET PHARMACEUTIQUE.** [Use of Differential Thermal Analysis in Identification of Polystyrene and Its Copolymers Used in the Food and Pharmaceutical Industry]. Polystyrene (PS) and its copolymers (SBR, ASA, SAN and ABS) have been studied by differential thermal analysis. These five families exhibit a large endothermic decomposition peak at about 380°C. The curves exhibit also one exothermic peak (ASA, SAN, ABS) or two (PS, SBR) which are larger and nearer for SBR than for PS. ASA, SAN and ABS copolymers are characterized by an endothermic peak shape (the slope of the ascending part has been computed and expressed for one gramme of sample). This method was used for identification of alimentary package and some pharmaceutical disposables. (Author abstract). 6 Refs. In French.

**Diffusion See Also POLYETHYLENES—Morphology; POLYMETHYL METHACRYLATE—Solutions.**

**083515 PORE SIZE EFFECTS ON DIFFUSION OF POLYSTYRENE IN DILUTE SOLUTION.** Rates of diffusion of linear polystyrene ( $MW\ 1.6-9.3 \times 10^5$ ) at dilute concentrations in tetrahydrofuran were measured as a function of pore size for thin membranes. The data for all molecular weights and pore sizes can be accurately correlated by a single relationship between  $D/D_0$  and  $R_s/R$ , where  $D$  and  $D_0$  are the diffusion coefficients for the pore and bulk solutions, respectively,  $R_s$  is the Stokes-Einstein radius of the polymer which is calculated from  $D_0$ , and  $R$  is the pore radius. Our results indicate that the hindrance effect of the pores on this linear polymer is greater than for a rigid sphere of the same Stokes-Einstein radius. (Edited author abstract) 28 refs.

Kathawalla, Imtiaz A. (Carnegie Mellon Univ, Pittsburgh, PA, USA); Anderson, John L. *Ind Eng Chem Res* v 27 n 5 May 1988 p 866-871.

**083516 CHAIN DIFFUSION OF POLYSTYRENE IN CS<sub>2</sub>.** This paper is focused on the issue of self-diffusion of polystyrene chains in CS<sub>2</sub> above and below the gelation region. By examining the self-diffusion we hope to shed some light on the nature of this gelation phenomenon. The authors show that polymer chains diffuse with a diffusion coefficient of the order of  $10^{-8}$  cm<sup>2</sup>/s, which is comparable to that of a moderately concentrated polystyrene solution at a comparable concentration. Secondly, the decay curves have 10-20% of a 'slow component' tail, which decreases in intensity as the temperature is increased and vanishes eventually above  $T_{gel}$ . 11 refs.

## Dissolution

**083517 DISSOLVED STATE OF ATACTIC POLYSTYRENE IN AROMATIC SOLVENTS: APPROACHES THROUGH <sup>1</sup>H NMR, FT-IR AND ADIABATIC COMPRESSIBILITY.** An attempt was made to interpret significant differences in thermodynamic parameters, including the concentration dependence coefficients  $p_1$  and  $p_2$  of the polymer-solvent interaction parameter  $\chi$ , Flory entropy parameter at infinite dilution  $\psi_0$ , Flory temperature  $\theta$ , observed between atactic polystyrene (PS) in aromatic and aliphatic solvents by the characteristic features of the dissolved state of PS in aromatic solvents. For this purpose, <sup>1</sup>H NMR spectra were measured on PS/benzene, cyclohexane, toluene, and methylcyclohexane systems and the infrared spectra and adiabatic compressibility were determined for the former two solvents. In PS/aromatic solvents H<sub>2</sub>, H<sub>3</sub>, and H<sub>4</sub>-phenyl proton peaks are shifted to a lower magnetic field than those in PS/aliphatic solvent, which was produced by hydrogenation of the aromatic solvent. The degree of solvation is slightly larger in benzene than in cyclohexane. (Edited author abstract) 15 refs.

## Electric Field Effects

**083518 EFFECT OF ELECTROLYTE CONCENTRATION AND CO-ION TYPE ON THE  $\zeta$ -POTENTIAL OF POLYSTYRENE LATICES.** High-frequency dielectric response measurements were performed on three monodisperse polystyrene latices at varying electrolyte concentrations. For one latex, the  $\zeta$ -potential and electrokinetic charge obtained from these measurements were compared with results obtained from microelectrophoresis. It appears that the high-frequency dielectric response technique probes the whole of the diffuse double layer and gives an estimation of the Outer Helmholtz plane potential  $\psi_d$ . To investigate the effect of co-ions on the  $\zeta$ -potential, microelectrophoresis experiments were performed on a single latex at varying electrolyte concentrations using potassium fluoride, chloride, bromide, and iodide as the indifferent electrolyte. Little difference was found among these electrolytes, suggesting the absence of adsorption of co-ions into the inner Helmholtz plane. A model is proposed for the polystyrene/electrolyte interface that invokes localized surface roughness to explain the observed electrokinetic maximum. (Edited author abstract) 21 refs.

Midmore, B.R. (Univ of Sydney, Aust); Hunter, R.J. *J Colloid Interface Sci* v 122 n 2 Apr 1988 p 521-529.

## Encapsulation

**083519 PREPARATION OF POLYELECTROLYTE-COATED p-H-SENSITIVE POLY(STYRENE) MICROCAPSULES AND THEIR APPLICATION TO INITIATION-CESSATION CONTROL OF AN ENZYME REACTION.** Poly(styrene) microcapsules, prepared by depositing the polymer around emulsified aqueous droplets, were coated with a synthesized polyelectrolyte; i.e., copolymer of maleic acid (MA) with methyl vinyl ether (MVE), copoly (MA,MVE), or with styrene (St), copoly (MA,St). The permeability of the capsule membrane was investigated under various pHs of the outer medium using n-propyl alcohol as a permeant. It became apparent that either copoly (MA,St)-or copoly (MA, MVE)-coated microcapsules function as a pH-sensitive capsule. In particular, the former showed a dramatic change of the permeability in response to small differences in pH (5-6). By reference to the viscometric and electrophoretic studies of both copolymers, these were interpreted as being due to a pH-induced alteration of the configuration of the copolymer coating on the surface of the capsule membrane. When sucrose was hydrolyzed in an aqueous suspension of the copoly (MA,St)-coated

capsules into which invertase was loaded, the hydrolytic reaction was initiated at pH 5.5 and stopped at pH 4.5. Such initiation cessation control was repeated reversibly without damaging the capsules. (Author abstract). 12 Refs.

Kokufuta, Etsuo (Univ of Tsukuba, Sakura-mura, Jpn); Shimizuk, Noboru; Nakamura, Isei. *Biotechnol Bioeng* v 32 n 3 Jul 20 1988 p 289-294.

## Fatigue

**083520 EFFECT OF DEFORMATION RATIO ON FIBRIL DEFORMATION IN FATIGUE OF POLYSTYRENE.** Small-angle X-ray scattering has been used to measure the deformation of craze fibrils during mechanical fatigue of polystyrene. The maximum deformation of the sample in the fatigue cycle was kept constant while the minimum deformation was varied. When the minimum deformation was 50% or more of the maximum, the load on the craze fibrils remained tensile. When the minimum deformation was reduced below this, the load on the fibrils became compressive and they buckled. The main effect of minimum sample deformation on fatigue life occurred in the regime where the fibrils remained straight. In this regime a decrease in minimum sample deformation caused a considerable decrease in fatigue life. At low minimum sample deformations the effects of minimum deformation on fatigue life were not large. These effects probably stem from the fibril strains involved in the deformation processes. (Author abstract) 7 refs.

**Fillers** See Also PLASTICS—Mechanical Properties.

**083521 ELECTRICAL CONDUCTIVITY OF POLYMERS CONTAINING CARBON BLACK.** Changes in volume resistivity with temperature of carbon-black-filled polymers and a random copolymer of styrene and butyl methacrylate were measured. Decreases in resistivity on increasing the temperature in the quiescent state are correlated with the observation of a yield stress at low shear rates in rheological studies. It is suggested that carbon black agglomerates at elevated temperature and forms an independent conductive network that prevents flow. (Edited author abstract) 20 refs.

**083522 POLYSTYRENE-TITANIA COMPOSITE AS A DIELECTRIC MATERIAL.** Ambient dielectric effects have been studied in rutile-polystyrene compacts as functions of frequency and composition to explore the possibility of their use as electronic materials and characterize them on the basis of existing theories. The systems reveal marked departures from the law of physical mixtures. The dielectric constant  $\epsilon'$  and loss  $\epsilon''$  increase with increasing titania content at each frequency; both parameters decrease with increasing frequency; both parameters decrease with increasing frequency. The extent of interfacial polarization is substantially augmented as the frequency is reduced. Heterodispersity evidenced from compact densities is a maximum at around 60 wt% titania where the dissimilar particles fit most loosely into one another forming fairly porous matrices. (Edited author abstract) 11 refs.

## Film

**083523 XPS ANALYSIS OF NH<sub>3</sub> PLASMA-TREATED POLYSTYRENE FILMS UTILIZING GAS PHASE CHEMICAL MODIFICATION.** Gas phase chemical modification (GCM) is found to be more preferable as a pretreatment for the XPS surface analysis of polymer materials than the conventional liquid phase

treatment because it can circumvent problems such as solvent contamination and swelling. The authors have tried the quantification of the surface composition successfully by estimating the yield of the reaction from model samples. GCM was then applied to correlate the surface composition of NH<sub>3</sub> plasma-treated polystyrene films with their cell-affinity. The amount of primary-amine and that of carboxylic acid were directly determined by GCM. (Edited author abstract) 12 refs.

## Flame Resistance

**083524 TOXICITY STUDIES CLEAR THE AIR FOR BROMINATED FRs.** The combustion products from a widely used flame-retardant plastic present no measurable health hazards from dioxins or furans, according to a just-released toxicity study. These findings were based on animal studies by an independent laboratory, using burn residues of FR high impact polystyrene (HIPS). The impact styrene is virtually the standard plastic for TV cabinets and a major user of decabromo diphenyl oxide (DBDPO). The work on FR-HIPS is the first phase of an industry-sponsored program to address allegations that plastics from FR systems based on polybrominated diphenyl oxides could generate toxicologically significant amounts of dioxins and furans when burned.

## Forming

**083526 MECHANISM OF FORMATION AND PROPERTIES OF POLYTRICHLOROBUTADIENE-POLYSTYRENE PAIRED POLYMERS AT HIGH CONVERSION.** At advanced stages of the synthesis of paired polymers of poly-1,1,2-trichlorobutadiene-1,3 with polystyrene (PS) under the conditions of a Friedel-Crafts reaction, the unequal macromolecular coils already paired at earlier reaction stages further react by means of the fragments that have so far been unaffected by the reaction. Hardly soluble or insoluble paired polymers are formed in this process. In parallel with the Friedel-Crafts reaction, dehydrochlorination of the polytrichlorobutadiene component of the paired macromolecules occurs at advanced reaction stages, although it is partly inhibited by the main reaction. (Edited author abstract) 11 refs.

## Fracture

**083527 CURVILINEAR CRACK LAYER PROPAGATION.** This letter describes an experiment designed to observe the effect of damage orientation on the direction of crack growth. The phenomenon reported emphasizes the influence of the stress heterogeneity on the crack-layer behavior. It also emphasizes the effects of damage on crack advance. In this experiment authors also presented a methodology to study curvilinear crack-layer propagation. Within the framework of the crack-layer formalism, the study of this phenomenon unveils new potentials for material-toughness evaluation. 10 refs.

## Grafting

**083528 ANIONIC GRAFTING OF POLYSTYRENE FROM CARBON BLACKS CATALYZED BY OLI GROUPS ON THE CARBON BLACK SURFACE IN THE PRESENCE OF CROWN ETHER.** Carbon black carrying OLI groups, which was prepared by the reaction of the oxygen-containing groups on the surface with n-butyllithium (BuLi), was unable to initiate anionic polymerization of styrene. However, anionic polymerization of styrene is initiated by OLI group on carbon black in the presence of a crown ether, such as 12-crown-4 and 18-crown-6. It was found that when carbon black was pretreated with excess BuLi, i.e., in the presence of free BuLi, the grafting ratio decreased to less than 20% because the formation of ungrafted polystyrene by free BuLi occurs preferentially to the propagation from the OLI groups on carbon black. (Edited author abstract) 17 refs.

**083529 ASYMMETRIC REDUCTIONS WITH POLYMER-SUPPORTED NADH MODELS.** Hantzsch esters have been chosen as models for the reducing coenzyme NADH. Chirality was introduced on the dihydropyridine ring with substituents derived from protected sugars. Chiral and non-chiral Hantzsch esters were grafted onto chloromethylated polystyrene and the reducing action of the polymers thus obtained was studied using prochiral ketones. The reduction by soluble models is catalyzed by magnesium, but the supported models exhibit a preferential solvation effect which hinders the action of the catalyst. The effects on reactivity and enantioselectivity are discussed. (Author abstract) 31 refs.

Zehani, Sadek (CNRS, Lyon, Fr); Gelbard, Georges. *React Polym Ion Exch Sorbents* v 6 n 2-3 Oct 1987, Sel Pap Presented at the 3rd Int Conf on Polym-Supported React in Org Chem, Jerusalem, Isr, Jul 6-11 1986 p 81-87.

## Halogenation

**083530 PLASMA FLUORINATION OF POLYSTYRENE.** ESCA and contact-angle measurements were used to characterize the surfaces of polystyrene films exposed to SF<sub>6</sub>, CF<sub>4</sub>, and C<sub>2</sub>F<sub>6</sub> plasmas. SF<sub>6</sub> plasmas cause loss of aromaticity in the polystyrene surface region via saturation of the phenyl ring and/or carbon-carbon bond breakage and subsequent fluorination. C<sub>2</sub>F<sub>6</sub> plasmas graft CF<sub>x</sub> radicals directly to the polystyrene surface without necessarily destroying the aromaticity of the polymer. CF<sub>4</sub> plasmas appear to be intermediate in character between SF<sub>6</sub> and C<sub>2</sub>F<sub>6</sub> plasmas. (Author abstract) 7 refs.

**083531 PREPARATION AND APPLICATION OF THE POLYMER-BOUND IODOXY FUNCTIONAL GROUP.** Poly(iodostyrene) was prepared at 90% functionalization by reaction of mercuric trifluoroacetate with 2% crosslinked polystyrene beads followed by treatment of the mercurated resin with one equivalent of iodine in refluxing THF. The iodated polymer yielded a polymeric reagent with 65% of the theoretical activity of poly(iodostyrene) upon reaction with three equivalents of peracetic acid. The activated reagent can be used for the oxidation of aromatic hydrocarbons to quinones, aromatic acetylenes to dicarbonyls, and sulfides to sulfoxides in fair to good yields. The major advantage of the polymeric reagent is that the spent reagent can be removed from the reaction medium by filtration. (Author abstract) 18 refs.

## Injection Molding

**083532 MATHEMATICAL MODELING OF THE PACKING AND COOLING STAGES FOR AN INJECTION MOLDING PROCESS.** The behavior of PS in disk and strip-shaped cavities during the packing and cooling stages for an injection molding process is studied by means of the finite difference method. Simulated results reveal that the model used in the present study for the packing stage can avoid the conflicting phenomena which appeared in T.S. Chung's model for one-dimensional flow. The results obtained by the two-stage model proposed in the present study for packing and cooling stages are better than that obtained by the unified model reported in the literature. It is also shown that the effects of shear rate and pressure on the melt viscosity during packing stage may not be neglected. (Edited author abstract) 19 refs.

**083533 MICROSCOPIC OBSERVATION OF ORDERED COLLOIDS IN SEDIMENTATION EQUILIBRIUM AND THE IMPORTANT ROLE OF DEBYE SCREENING LENGTH. 3. HEAVY AND MONODISPERSE POLYSTYRENE TYPE SPHERES IN AQUEOUS SOLUTION OF NEUTRAL POLYMERS.** The ordered structures are observed directly by the metallurgical microscope for the heavy (specific gravity=1.50) and monodisperse type spheres in sedimentation equilibrium and in the presence of neutral polymers, polyvinylalcohol (PVA), polyethylene glycol (PEG), polyvinylpyrrolidone (PVP), hydroxypropylcellulose (HPC), and polyacrylamide (PAA<sub>m</sub>). The intersphere distances in the ordered lattices decrease by the addition of neutral polymer in the order, PVA < PEG < PVP < HPC < PAA<sub>m</sub>. These effects of neutral polymers are reasonably well-explained by the intersphere repulsion from the electrical double layer interaction, which is influenced by the polymer adsorption on the latex surface by the hydrophobic and/or dipole-dipole interactions. (Author abstract) 43 refs.

Okubo, T. *Colloid Polym Sci* v 265 n 7 Jul 1987 p 597-603.

**083534 NONIONIC LATICES IN AQUEOUS MEDIA - PART I. PREPARATION AND CHARACTERIZATION OF POLYSTYRENE LATICES.** A series of non-ionic polystyrene latices in aqueous media containing particles with a narrow size distribution have been prepared using a nonyl phenol poly(ethylene glycol) condensate as the surfactant, methoxy poly(ethylene glycol) methacrylate as the comonomer/stabilizer, and ascorbic acid/hydrogen peroxide as the initiator system. As a control synthesis for comparison with the above latex, a charge stabilized polystyrene latex was prepared, using an anionic surfactant and potassium persulfate as the initiator. Latices employing a combination of charge plus steric stabilization mechanisms were also prepared, in

order to investigate the effect of the non-ionic surfactant and the comonomer/stabilizer. The particle size of the latices was measured by transmission electron microscopy, the surface charge density by conductimetric titration and the glass transition temperature of the polymer by differential scanning calorimetry. (Edited author abstract) 21 refs.

**083535 POLYSTYRENE AND POLYSTYRENE-BUTADIENE LATEXES STABILIZED BY POLY(N-ISOPROPYLACRYLAMIDE).** Latexes stabilized by poly(N-isopropylacrylamide) (polyNIPAM) were presented by polymerizing NIPAM in the presence of polystyrene and polystyrene-butadiene latex or by styrene emulsion polymerization in the presence of NIPAM. In 0.01 M CaCl<sub>2</sub>, polyNIPAM stabilized latexes exhibited critical flocculation temperatures in the range 32-35°C, which is approximately equal to the lower critical solution temperature of polyNIPAM in water. Partial substitution of NIPAM with some acrylamide (AM) gave higher flocculation temperatures. Coagulation studies with cleaned latex indicated that the polyNIPAM or polyNIPAM-co-AM polymer chains were anchored to the latex particle surfaces. (Author abstract) 14 refs.

Pelton, R.H. (Pulp & Paper Research Inst of Canada, Pointe Claire, Que, Can). *J Polym Sci Part A* v 26 n 1 Jan 1988 p 9-18.

**083536 EFFECT OF pH ON EMULSION POLYMERIZATION OF STYRENE IN THE PRESENCE OF AN AMPHOTERIC EMULSIFIER.** An emulsion polymerization of styrene in the presence of an amphoteric emulsifier of the betaine type; N,N-dimethyl-N-lauryl-betaine (LNB), has been studied at various pH values. The relationships between the physicochemical properties of LNB aqueous solutions, the emulsion polymerization process and the characteristics of the synthesized latex particles were studied under various pH conditions. The polymerization rate and the particle number concentration decreased with increasing pH of LNB aqueous solution and changed in shape at both ca. pH 4 and pH 8-10. The properties of LNB aqueous solution also changed with the pH and changed in shape at the same pH as that of the emulsion polymerization. These pH values were in good agreement with the pH at which the LNB molecule changed its ionic form. The number of synthesized latex particles was proportional to the number of LNB micelles in the solution, below pH 10. The particle size of the synthesized latex particles and the molecular weight of the latex polymers also changed with the properties of LNB aqueous solutions, accompanying the change of the ionic form of LNB molecules. (Author abstract) 19 refs.

**083537 REVERSIBLE AGGREGATION: PART I. REVERSIBLE FLOCCULATION MONITORED BY TURBIDITY MEASUREMENTS.** The aggregation of four separate polystyrene latices, ranging in diameter from 210 nm to ca. 1 µm, using sodium chloride and magnesium sulphate as the electrolytes, has been examined turbidimetrically. The reversibility of the aggregation was examined using a dialysis technique. It was found that for large particle size latices aggregation was reversible in sodium chloride even at concentrations up to 0.5 mol dm<sup>-3</sup>. The aggregation of smaller particles was not reversible. The aggregation of large particles in magnesium sulphate solutions was not readily reversed by dialysis. The latter result does not appear to agree with theoretical predictions. (Author abstract) 17 refs.

**083538 NARROW SIZE DISTRIBUTION POLYSTYRENE LATEXES PREPARED IN THE PRESENCE OF AMPHOTERIC SULFOBETAINE SURFACTANTS.** Polystyrene latexes with a narrow size distribution were prepared with a large range of particle sizes (from 40 to 800 nm) in the presence of various amphoteric sulfo betaine surfactants. The influence of the nature of the surfactant and of the ionic strength, the pH and solid content were studied. The results are discussed and compared with those obtained using sodium dodecyl sulfate or in the absence of surfactants. (Author abstract) 20 refs.

**083539 DIFFUSIOPHORESIS OF LATEX PARTICLES IN ELECTROLYTE GRADIENTS.** Transport rates of 0.1-µm diameter polystyrene latex spheres through porous membranes separating aqueous solutions differing in electrolyte concentration were measured to determine the diffusioelectric velocities of the particles. Two types of experiments were performed. In the first the initial particle concentration was the same on both sides of the membrane; after an electrolyte concentration difference was created, the accumulation of particles on one side and the depletion on the other side were measured as a function of time. These experiments convincingly demonstrate the phenomenon of diffusioelectricity because there is no other obvious explanation for the creation of a particle gradient from a system initially uniform in particle concentration. In the second type of experiment particles were placed only on one side of the membrane, and the electrolyte gradient was established such that it augmented the particle transport rate down the particle concentration gradient. Enhancements of 50 times Brownian diffusion of the particles were observed when there was a 70% change in electrolyte concentration across the membrane. (Edited author abstract) 39 refs.

## Manufacture

**083540 POLYSTYRENE AND STYRENE COPOLYMERS. I. THEIR MANUFACTURE AND APPLICATION.** The manufacturing processes for polystyrene (PS) and its copolymers, including styrene-acrylonitrile (SAN), high impact polystyrene (HIPS), acrylonitrile-butadiene-styrene (ABS), styrene-butadiene latex (SBR for coatings), styrene-butadiene block copolymers (SBS), and styrene-acrylate copolymers (SMMA), are discussed and illustrated. The synthetic methods for such products are bulk, emulsion, suspension, and free radical polymerization techniques, all either in batch or in continuous operations. By comparison, it was found that continuous bulk is the most economical process among the above-mentioned polymerization methods. However, the suspension method is still the only way to make expandable polystyrene beads (EPS). (Edited author abstract) 17 refs.

Ku, Ping L. (PLK Consultant, Chester, VA, USA). *Adv Polym Technol* v 8 n 2 Summer 1988 p 177-196.

**083541 POLYSTYRENE AND STYRENE COPOLYMERS: THEIR MANUFACTURE AND APPLICATION. II.** Three decades ago, practically all polystyrene and its derived copolymers (except SBR rubber) were manufactured via suspension polymerization, due to the fact that its capital expenditure was low. In recent years, the labor costs have soared. In order to be competitive, the industry had to develop an alternative cheaper process to remain solvent. The most successful new low-cost process is bulk continuous polymerization. Therefore, most processes for manufacturing the polystyrene and its allied copolymers discussed in this study emphasized the utilization of the bulk continuous process. Some of the topics discussed include high-impact polysty-

rene manufacture, raw materials, procedures, processing conditions, and properties of polystyrene products. Acrylonitrile-butadiene-styrene terpolymer is also covered. 21 Refs.

## Molecular Structure

**083542 POLYSTYRENES WITH STRUCTURALLY DIFFERENT OLIGOSILOXANES AS p-SUBSTITUENTS FOR OXYGEN PERMEABLE MEMBRANE MATERIALS.** Polystyrenes with structurally different oligosiloxanes as p-substituents were synthesized and the selective oxygen permeation through the polymer film was studied. It was found that the structure of the p-oligosiloxane substituents had great effects not only on the glass transition temperature of the polymer but also on the oxygen permeation behavior through the polymer film. Trimethylsiloxy groups, especially, were shown to play an essential role in enhancing the permeability. (Author abstract) 9 refs.

**083544 MULTIPLE GLASS TRANSITIONS IN BIMODAL POLYSTYRENE MIXTURES.** Monomers and oligomers are in general compatible with their polymer above the melting point of the polymer. When crystallization can be avoided, this type of mixture should produce an amorphous compatible blend with a single glass transition temperature. However, mixtures of bimodal molecular weight distribution of sufficiently high molecular weight differences may easily be thermally treated to show either a single glass transition temperature or multiple glass transition temperatures, as a consequence of non-uniform distribution of relaxation times, which may result from a separation into concentration or density domains. (Author abstract) 7 refs.

Chang, Shu-Sing (NBS, Gaithersburg, MD, USA). *Polym Commun (Guildford Engl)* v 29 n 2 Feb 1988 p 33-35.

**083545 DIMENSIONS OF ULTRAHIGH MOLECULAR WEIGHT POLYSTYRENE IN CYCLOHEXANE BELOW THE  $\Theta$  TEMPERATURE.** In this work, we investigated the temperature dependence of dimensions of a very high molecular weight ( $M_w$  to approx.  $41 \times 10^6$  g/mol) PS sample in cyclohexane below the  $\Theta$  temperature by means of laser light scattering. Experimental results show that (1) degradation of very long polymer chains occurs readily at very dilute polymer concentrations ( $C \leq 10^{-6}$  g/g) for our high molecular weight PS sample. (2) In coil-to-globule transition studies, the polydispersity effect becomes a critical issue. As it is difficult to prepare ultrahigh molecular weight PS samples

with a very narrow molecular weight distribution, the advantage of this ultrahigh molecular weight PS sample was overshadowed by its unexpectedly broad polydispersity. 16 refs.

Park, Il Hyun (State Univ of New York at Stony Brook, Stony Brook, NY, USA); Fetters, Lewis; Chu, Benjamin. *Macromolecules* v 21 n 4 Apr 1988 p 1178-1180.

**083546 MOLECULAR WEIGHT EFFECTS IN THE RELAXATION OF ORIENTATION OF POLYSTYRENE CHAINS AS REVEALED BY INFRARED DICHROISM.** The relaxation of orientation of narrow distribution polystyrenes of different molecular weights is studied over 4 decades of time by infrared dichroism and compared to the predictions of the Doi-Edwards and related models. The behavior at short times appears to be independent of the molecular weight, whereas molecular weight effects at longer time are observed, as predicted by the theory. A careful comparison between theory and experiment shows that the kinetics of the relaxation at short times are slower than predicted by the model. The experimental behavior at longer times is in good agreement, especially for the highest molecular weights, with the predictions of a self-consistent treatment including a process of equilibration across slip-links. (Author abstract) 34 refs.

## Oxidation

**083547 KINETICS AND MECHANISM OF THE FORMATION AND BREAKDOWN OF THE HYDROPEROXIDE IN THE COURSE OF OXIDATION OF POLYSTYRENE.** It is shown that the effective breakdown constant  $k_{3,eff}$  of the PS hydroperoxide (ROOH) measured from the ratio of the steady rate of oxidation to  $[ROOH]_{st}$  and kinetics of accumulation of ROOH rises with increase in the oxygen pressure. Breakdown of ROOH PS in vacuo takes place as a set of two monomolecular reactions with rate constants differing by a decimal order of magnitude. The fraction of the rapidly decaying hydroperoxide rises linearly with increase in the total concentration of ROOH. The authors postulate rapid breakdown of the polyfunctional polymer ROOHs, the rate of formation of which is proportional to  $[ROOH]$ . The kinetic scheme on the basis of this assumption quantitatively describes the experimental findings. (Author abstract) 13 refs.

## Phase Diagrams

**083548 THERMOREVERSIBLE GELATION OF ISOTACTIC POLYSTYRENE: THERMODYNAMICS AND PHASE DIAGRAMS.** The thermodynamics of thermoreversible gelation of isotactic polystyrene in cis-decalin, trans-decalin, and 1-chlorodecane was investigated by using differential scanning calorimetry. The gel formation and the gel melting were studied as a function of various parameters such as the cooling or heating rate and the polymer molecular weight. The temperature-concentration phase diagrams were established from both cooling and heating experiments. It is found that the shape of the phase diagram is the same in heating or in cooling, but that for cis-decalin differs from the one for trans-decalin. (Edited author abstract) 18 refs.

## Physical Properties

**083549 DYNAMIC LIGHT SCATTERING MEASUREMENTS ON THE POLYSTYRENE/ETHYL ACETATE SYSTEM AT SEMI-DILUTE CONCENTRATIONS AS A FUNCTION OF TEMPERATURE.** Measurements of autocorrelation functions extending over a broad time range are reported for a sample of polystyrene in ethyl acetate as a function of temperature between  $-44^\circ\text{C}$  and  $70^\circ\text{C}$ . The corresponding spectra of decay times are obtained by two mathematical methods. The existence of three dynamic processes is shown and their temperature and angular behaviour are studied. (Edited author abstract) 20 refs.

Stepanek, Petr; Jakes, Jaromir; Konak, Cesmir; Johnsen, Robert; Brown, Wyn. *Polym Bull (Berlin)* v 18 n 2 Aug 1987 p 161-167.

**083550 DIELECTRIC AND MECHANICAL RELAXATION TIMES OF A POLYMER USING INTERMOLECULAR FORCES.** Expressions are derived for the dielectric and mechanical base relaxation times of a polymer above its glass transition temperature. Coupled oscillator theory is invoked to show that a low-frequency dielectric relaxation should have a relaxation time proportional to the degree of polymerization, N. A damped linear array is used to calculate the base mechanical relaxation time,  $\tau_p$ . The principles of intermolecular forces and dielectric energy dissipation are taken from previous work of the author in order to model the frictional drag and elastic constants required by the equation of motion of the damped linear array. (Edited author abstract) 9 refs.

Porter, D. (Dow Chemical, Terneuzen, Neth). *Polymer* v 29 n 3 Mar 1988 p 541-544.

**083551 SITE-SPECIFIC LABELING AND THE DISTRIBUTION OF FREE VOLUME IN GLASSY POLYSTYRENE.** Free volume environments at different sites along the polystyrene molecule have been evaluated by site-specific labeling with azobenzene chromophores. The sites investigated are the regions around the chain ends, the chain sides, and the chain centers along the backbone. Also investigated was the free volume of the least constrained regions between the chains by the use of free probes not attached to the polymer molecule. Trans  $\rightarrow$  cis photoisomerization kinetics of the labels and the free probe were studied at 70, 80, and  $90^\circ\text{C}$  as a function of annealing time following cooling from the melt. (Edited author abstract) 35 refs.

## Polymerization

**083552 QUANTITATIVE RELATIONSHIPS OF GRAFT POLYMERIZATION OF POLYSTYRENE AND STYRENE-DIVINYLBENZENE COPOLYMER ON POLYPROPYLENE FIBERS.** The purpose of this work was to study the quantitative relationships of polystyrene grafting on polypropylene (PP) fibers, using a direct method for generation of radicals. It is shown that the direct radiation method for grafting styrene from solutions in methyl alcohol is highly effective when small amounts ( $\geq 0.1\%$ ) of divinylbenzene are introduced into the styrene. Polypropylene fibers with grafted styrene-divinylbenzene copolymer can be used for production of strongly basic and strongly acidic ion-exchange fibers having high exchange capacity and chemical stability and satisfactory mechanical properties. 10 refs.

## Porosity

**083553 FISHER-TROPSCH SYNTHESIS CATALYZED BY IRON CATALYST SUPPORTED ON POROUS POLYMERS. I. SYNTHESIS OF THE SUPPORTED CATALYST AND STUDY OF THE**

**REPARTITION OF THE CATALYST IN THE POLYMERIC SUPPORT.** Macroporous styrene-divinylbenzene and 4-vinylpyridine divinylbenzene polymers were used as supports for an iron Fischer-Tropsch catalyst. The catalyst was based on iron in the zero-valent state. Two methods of preparation were tested: reduction of the catalyst after or before introduction into the polymeric support. In both cases, the dispersion of the catalytic species in the polymeric support was determined by electron probe X-ray microanalysis. It was shown that reduction of the catalyst after diffusion into the polymeric support gives a homogeneous distribution of the catalyst in the beads, whereas the diffusion of already reduced catalyst into the support leads to a heterogeneous mixture of species. (Author abstract) 19 refs.
